- Specify *tablespace* to indicate the user's temporary tablespace. Specify TEMPORARY TABLESPACE to indicate a shared temporary tablespace. Specify LOCAL TEMPORARY TABLESPACE to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify CDB\$DEFAULT to use the CDB-wide default temporary tablespace.
- Specify *tablespace_group_name* to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by *tablespace_group_name*. Local temporary tablespaces cannot be part of a tablespace group.

Restrictions on Temporary Tablespace

This clause is subject to the following restrictions:

- The tablespace must be a temporary tablespace and must have a standard block size.
- The tablespace cannot be an undo tablespace or a tablespace with automatic segment-space management.

① See Also

- *Oracle Database Administrator's Guide* for information about tablespace groups and *Oracle Database Security Guide* for information on assigning temporary tablespaces to users
- [CREATE TABLESPACE](#) for more information on undo tablespaces and segment management
- "[Assigning a Tablespace Group: Example](#)"

QUOTA Clause

Use the QUOTA clause to specify the maximum amount of space the user can allocate in the tablespace.

A CREATE USER statement can have multiple QUOTA clauses for multiple tablespaces.

UNLIMITED lets the user allocate space in the tablespace without bound.

The maximum amount of space that you can specify is 2 terabytes (TB). If you need more space, then specify UNLIMITED.

Restriction on the QUOTA Clause

You cannot specify this clause for a temporary tablespace.

① See Also

[size clause](#) for information on that clause and *Oracle Database Security Guide* for more information on assigning tablespace quotas

PROFILE Clause

Specify the profile you want to assign to the user. The profile limits the amount of database resources the user can use. If you omit this clause, then Oracle Database assigns the DEFAULT profile to the user.

You can use the CREATE USER statement to create a new user, and associate the user with a profile that has the PASSWORD_ROLLOVER_TIME configured.

You must first set the password rollover period using CREATE PROFILE or ALTER PROFILE.

In the example u1 is the user, with password p1. prof1 is the profile with PASSWORD_ROLLOVER_TIME set.

```
CREATE USER u1 IDENTIFIED BY p1 PROFILE prof1 ;
```

① Note

Oracle recommends that you use the Database Resource Manager to establish database resource limits rather than SQL profiles. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to *Oracle Database Administrator's Guide*.

① See Also

- [GRANT](#) and [CREATE PROFILE](#)
- Configuring Authentication

PASSWORD EXPIRE Clause

Specify PASSWORD EXPIRE if you want the user's password to expire. This setting forces the user or the DBA to change the password before the user can log in to the database.

ACCOUNT Clause

Specify ACCOUNT LOCK to lock the user's account and disable access. Specify ACCOUNT UNLOCK to unlock the user's account and enable access to the account. The default is ACCOUNT UNLOCK.

ENABLE EDITIONS

This clause is not reversible. Specify ENABLE EDITIONS to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in schemas that are not editions-enabled cannot be editioned.

Note the following before enabling editions with ALTER USER:

- Enabling editions is not a live operation.
- When a database is upgraded from Release 11.2 to Release 12.1, users who were enabled for editions in the pre-upgrade database are enabled for editions in the post-upgrade database and the default schema object types are editionable in their schemas. The default schema object types are displayed by the static data dictionary view `DBA_EDITIONED_TYPES`. Users who were not enabled for editions in the pre-upgrade database are not enabled for editions in the post-upgrade database and no schema object types are editionable in their schemas.
- To see which users already have editions enabled, see the `EDITIONS_ENABLED` column of the static data dictionary view `DBA_USERS` or `USER_USERS`.

Restriction on Enabling Editions

The `FOR` clause is ignored when used with `ENABLE EDITIONS`. This only applies to the `CREATE USER` statement, not the `ALTER USER` statement.

You cannot enable editions for any schemas supplied by Oracle.

① See Also

- *Enabling Editions for a User*
- *Oracle Database Reference* for more information about the `V$EDITIONABLE_TYPES` dynamic performance view

CONTAINER Clause

The `CONTAINER` clause applies when you are connected to a CDB. However, it is not necessary to specify the `CONTAINER` clause because its default values are the only allowed values.

- To create a common user, you must be connected to the root. You can optionally specify `CONTAINER = ALL`, which is the default when you are connected to the root.
- To create a local user, you must be connected to a PDB. You can optionally specify `CONTAINER = CURRENT`, which is the default when you are connected to a PDB.

While creating a common user, any default tablespace, temporary tablespace, or profile specified using the following clauses must exist in all the containers belonging to the CDB:

- `DEFAULT TABLESPACE`
- `TEMPORARY TABLESPACE`
- `QUOTA`
- `PROFILE`

If these objects do not exist in all the containers, the `CREATE USER` statement fails.

READ ONLY | READ WRITE

Use this clause to set `READ ONLY` access to a local PDB user.

With read-only access, the local PDB user is not permitted to execute any write operations on the PDB they connect to. The session operates as if the database is open in read-only mode.

Specify `READ WRITE` to set `READ WRITE` access to a local user.

You must have the `CREATE USER` privilege to execute this statement.

You can view the state of a local user in the *_USERS view.

Examples

All of the following examples use the example tablespace, which exists in the seed database and is accessible to the sample schemas.

Creating a Database User: Example

If you create a new user with PASSWORD EXPIRE, then the user's password must be changed before the user attempts to log in to the database. You can create the user sidney by issuing the following statement:

```
CREATE USER sidney
  IDENTIFIED BY out_standing1
  DEFAULT TABLESPACE example
  QUOTA 10M ON example
  TEMPORARY TABLESPACE temp
  QUOTA 5M ON system
  PROFILE app_user
  PASSWORD EXPIRE;
```

The user sidney has the following characteristics:

- The password out_standing1
- Default tablespace example, with a quota of 10 megabytes
- Temporary tablespace temp
- Access to the tablespace SYSTEM, with a quota of 5 megabytes
- Limits on database resources defined by the profile app_user (which was created in ["Creating a Profile: Example"](#))
- An expired password, which must be changed before sidney can log in to the database

Creating External Database Users: Examples

The following example creates an external user, who must be identified by an external source before accessing the database:

```
CREATE USER app_user1
  IDENTIFIED EXTERNALLY
  DEFAULT TABLESPACE example
  QUOTA 5M ON example
  PROFILE app_user;
```

The user app_user1 has the following additional characteristics:

- Default tablespace example
- Default temporary tablespace example
- 5M of space on the tablespace example and unlimited quota on the temporary tablespace of the database
- Limits on database resources defined by the app_user profile

To create another user accessible only by an operating system account, prefix the user name with the value of the initialization parameter OS_AUTHENT_PREFIX. For example, if this value is "ops\$", then you can create the externally identified user external_user with the following statement:

```
CREATE USER ops$external_user
  IDENTIFIED EXTERNALLY
  DEFAULT TABLESPACE example
  QUOTA 5M ON example
  PROFILE app_user;
```

Creating a Global Database User: Example

The following example creates a global user. When you create a global user, you can specify the X.509 name that identifies this user at the enterprise directory server:

```
CREATE USER global_user
  IDENTIFIED GLOBALLY AS 'CN=analyst, OU=division1, O=oracle, C=US'
  DEFAULT TABLESPACE example
  QUOTA 5M ON example;
```

Creating a Common User in a CDB

The following example creates a common user called `c##comm_user` in a CDB. Before you run this `CREATE USER` statement, ensure that the tablespaces `example` and `temp_tbs` exist in all of the containers in the CDB.

```
CREATE USER c##comm_user
  IDENTIFIED BY comm_pwd
  DEFAULT TABLESPACE example
  QUOTA 20M ON example
  TEMPORARY TABLESPACE temp_tbs;
```

The user `comm_user` has the following additional characteristics:

- The password `comm_pwd`
- Default tablespace `example`, with a quota of 20 megabytes
- Temporary tablespace `temp_tbs`

CREATE VECTOR INDEX

Purpose

Vector indexes speed up vector searches and are either exact search indexes or approximate search indexes. An exact search gives 100% accuracy at the cost of heavy compute resources. Approximate search indexes, also called vector indexes, trade accuracy for performance.

Vectors are grouped or connected together based on similarity, where similarity is determined by their relative distance to each other. Greedy searches are done across these groups and connections to find the best, closest match to the query vector being searched for. A search using a vector index is called an approximate search.

There are two vector indexes supported in vector search: IVF (Inverted File) Flat index and HNSW (Hierarchical Navigable Small Worlds) index. IVF Flat (also simply called IVF) is a partitioned-based index, while HNSW is a graph-based index. All partition based indexes are classified as Neighbor Partition Vector Index, and all graph-based indexes are classified as In-Memory Neighbor Graph Vector Index.

vector_index_parameters_hnsw_clause::=

vector_index_parameters_ivf_clause::=

vector_index_hnsw_replication_clause

Semantics

vector_column | expr

vector_column: name of column of type VECTOR.

expr: use to specify a function-based HNSW index similar to normal indexes. A function-based HNSW index is an index created on an expression instead of a vector column. It computes the value of an expression and stores it in the index. The index expression can be an arithmetic or conditional expression.

See Function Based Hierarchical Navigable Small World Index of the *AI Vector Search User's Guide*.

INCLUDE

See *Included Columns* of the *AI Vector Search User's Guide* for semantics.

vector_index_parameters_hnsw_clause

HNSW Specific Parameters

NEIGHBORS and M are equivalent and represent the maximum number of neighbors a vector can have on any layer, except the last layer, where a vector can have up to 2M neighbors.

EFCONSTRUCTION represents the maximum number of closest vector candidates considered at each step of the search during insertion.

The valid range for HNSW vector index parameters are:

- ACCURACY: > 0 and <= 100
- DISTANCE: EUCLIDEAN, L2_SQUARED (aka EUCLIDEAN_SQUARED), COSINE, DOT, MANHATTAN, HAMMING

If you do not specify DISTANCE *metric_name*, the default metric COSINE is used.

- TYPE : HNSW
- NEIGHBORS: >= 2 and <= 2048
- EFCONSTRUCTION: > 0 and <= 65535
- *rescore_factor*: integer between 1 and 100

OFFLOAD_CREDENTIAL_NAME: refers to the credential name.

OFFLOAD_URL: refers to the address of the remote compute server.

For more on OFFLOAD parameters see Use the Vector Index Service *Private AI Services Container User's Guide*.

quantization_algorithm: the algorithm used for quantization

vector_index_parameters_ivf_clause

IVF Parameters

NEIGHBOR PARTITIONS determines the number of centroid partitions that are created by the index.

SAMPLES_PER_PARTITION decides the total number of vectors that are passed to the clustering algorithm (number of samples per partition times the number of neighbor partitions). Note, that

passing all the vectors would significantly increase the total time to create the index. Instead, aim to pass a subset of vectors that can capture the data distribution.

MIN_VECTORS_PER_PARTITION represents the target minimum number of vectors per partition. Aim to trim out any partition that can end up with fewer than 100 vectors. This may result in lesser number of centroids. Its values can range from 0 (no trimming of centroids) to num_vectors (would result in 1 neighbor partition).

The valid range for IVF vector index parameters are:

- ACCURACY: > 0 and <= 100
- DISTANCE: EUCLIDEAN, L2_SQUARED (aka EUCLIDEAN_SQUARED), COSINE, DOT, MANHATTAN, HAMMING
If you do not specify DISTANCE *metric_name*, the default metric COSINE is used.
- TYPE : IVF
- NEIGHBOR PARTITIONS: >= 1 and <= 10000000
- SAMPLES_PER_PARTITION: from 1 to (*num_vectors/neighbor_partitions*)
- MIN_VECTORS_PER_PARTITION: from 0 (no trimming of centroid partitions) to total number of vectors (would result in 1 centroid partition)
- NEIGHBOR PARTITION GROUPING: one of ON or OFF. Default is OFF.

See Neighbor Partition Vector Index of the *AI Vector Search User's Guide*.

QUANTIZATION Clause

- *quantization_type*: SCALAR.
- *compression_ratio* indicates by how much to compress the vectors. Acceptable values are 2,4,8.

vector_index_hnsw_replication_clause

- If neither DUPLICATE nor DISTRIBUTE clause is specified, the default is DUPLICATE ALL.
- Specifying DISTRIBUTE with no other qualifiers defaults to DISTRIBUTE AUTO.
- In DISTRIBUTE AUTO mode:
 - Non-partitioned tables are distributed by ROWID RANGE.
 - Partitioned or sub-partitioned tables are distributed by [SUB]PARTITION.
- You may specify either DUPLICATE ALL or DISTRIBUTE, but not both.

See Manage the Different Categories of Vector Indexes

ONLINE

Specify ONLINE to rebuild HNSW and IVF indexes online. This means that the indexes can remain open for updates while they are rebuilt.

See Online Hierarchical Navigable Small World Index of the *AI Vector Search User's Guide*.

LOCAL

Specify LOCAL to create an index for each partition or sub partition of a partitioned table.

See Local HNSW Indexes of the *AI Vector Search User's Guide*.

Examples

```
CREATE VECTOR INDEX galaxies_hnsw_idx ON galaxies (embedding) ORGANIZATION INMEMORY  
NEIGHBOR GRAPH  
DISTANCE COSINE  
WITH TARGET ACCURACY 95;
```

```
CREATE VECTOR INDEX galaxies_hnsw_idx ON galaxies (embedding) ORGANIZATION INMEMORY  
NEIGHBOR GRAPH  
DISTANCE COSINE  
WITH TARGET ACCURACY 90 PARAMETERS (type HNSW, neighbors 40, efconstruction 500);
```

```
CREATE VECTOR INDEX galaxies_ivf_idx ON galaxies (embedding) ORGANIZATION NEIGHBOR  
PARTITIONS  
DISTANCE COSINE  
WITH TARGET ACCURACY 95;
```

```
CREATE VECTOR INDEX galaxies_ivf_idx ON galaxies (embedding) ORGANIZATION NEIGHBOR  
PARTITIONS  
DISTANCE COSINE  
WITH TARGET ACCURACY 90 PARAMETERS (type IVF, neighbor partitions 10);
```

CREATE VIEW

Purpose

Use the CREATE VIEW statement to define a **view**, which is a logical table based on one or more tables or views. A view contains no data itself. The tables upon which a view is based are called **base tables**.

You can create an **object view** or a relational view that supports LOBs, object types, REF data types, nested table, or varray types on top of the existing view mechanism. An object view is a view of a user-defined type, where each row contains objects, each object with a unique object identifier.

You can create a XMLType view, which is similar to an object view but displays data from XMLSchema-based tables of XMLType.

① See Also

- *Oracle AI Database Concepts*, *Oracle AI Database Development Guide*, and *Oracle AI Database Administrator's Guide* for information on various types of views and their uses
- *Oracle XML DB Developer's Guide* for information on XMLType views
- [ALTER VIEW](#) and [DROP VIEW](#) for information on modifying a view and removing a view from the database

Prerequisites

To create a view in your own schema, you must have the CREATE VIEW system privilege. To create a view in another user's schema, you must have the CREATE ANY VIEW system privilege.

To create a subview, you must have the UNDER ANY VIEW system privilege or the UNDER object privilege on the superview.

The owner of the schema containing the view must have the privileges necessary to either select (READ or SELECT privilege), insert, update, or delete rows from all the tables or views on which the view is based. The owner must be granted these privileges directly, rather than through a role.

To use the basic constructor method of an object type when creating an object view, one of the following must be true:

- The object type must belong to the same schema as the view to be created.
- You must have the EXECUTE ANY TYPE system privileges.
- You must have the EXECUTE object privilege on that object type.

① See Also

[SELECT](#), [INSERT](#), [UPDATE](#), and [DELETE](#) for information on the privileges required by the owner of a view on the base tables or views of the view being created

create_view::=

object_view_clause::=***(inline_constraint::= and out of line_constraint::=)******XMLType_view_clause::=******XMLSchema_spec::=******annotations_clause::=***For the full syntax and semantics of the *annotations_clause* see [annotations_clause](#).***subquery_restriction_clause::=***

Semantics

OR REPLACE

Specify **OR REPLACE** to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranteeing object privileges previously granted on it.

INSTEAD OF triggers defined on a conventional view are dropped when the view is re-created. DML triggers defined on an editing view are retained when an editing view is re-created. However, such triggers can be rendered permanently invalid if the editing view has changed so that it can no longer be compiled—for example if an editing view column referenced in the trigger definition has been dropped.

If any materialized views are dependent on *view*, then those materialized views will be marked **UNUSABLE** and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.

You cannot replace a conventional view with an editing view or an editing view with a conventional view. See *Oracle AI Database Development Guide* for more information on editing views.

When a column in a view is removed and a data grant is present on the column with column security, then the data grant becomes invalid and results in a run-time error. You can query the **DBA_DATA_GRANTS** view to find the invalid column to replace the data grant. You can also fix the invalid data grant by adding the column back to the view definition.

📘 See Also

- **DBA_DATA_GRANTS** of the *Database Reference*.
- [ALTER MATERIALIZED VIEW](#) for information on refreshing invalid materialized views
- *Oracle AI Database Concepts* for information on materialized views in general
- [CREATE TRIGGER](#) for more information about the **INSTEAD OF** clause

FORCE

Specify **FORCE** if you want to create the view regardless of whether the base tables of the view or the referenced object types exist or the owner of the schema containing the view has privileges on them. These conditions must be true before any **SELECT**, **INSERT**, **UPDATE**, or **DELETE** statements can be issued against the view.

If the view definition contains any constraints, **CREATE VIEW ... FORCE** fails if the base table does not exist or the referenced object type does not exist. **CREATE VIEW ... FORCE** also fails if the view definition names a constraint that does not exist.

NO FORCE

Specify NOFORCE if you want to create the view only if the base tables exist and the owner of the schema containing the view has privileges on them. This is the default.

EDITIONING

Use this clause to create an **editioning view**. An editioning view is a single-table view that selects all rows from the base table and displays a subset of the base table columns. You can use an editioning view to isolate an application from DDL changes to the base table during administrative operations such as upgrades. You can obtain information about the relationship of existing editioning view to their base tables by querying the USER_, ALL_, and DBA_EDITIONING_VIEW data dictionary views.

The owner of an editioning view must be editions-enabled. Refer to [ENABLE EDITIONS](#) for more information.

Notes on Editioning Views

Editioning views differ from conventional views in several important ways:

- Editioning views are intended only to select and provide aliases for a subset of columns in a table. Therefore, the syntax for creating an editioning view is more limited than the syntax for creating a conventional view. Any violation of the restrictions that follow causes the creation of the view to fail, even if you specify FORCE.
- You can create DML triggers on editioning views. In this case, the database considers the editioning view to be the base object of the trigger. Such triggers fire when a DML operation target the editioning view itself. They do not fire if the DML operation targets the base table.
- You cannot create INSTEAD OF triggers on editioning views.

Restrictions on Editioning Views

Editioning views are subject to the following restrictions:

- Within any edition, you can create only one editioning view for any single table.
- You cannot specify the *object_view_clause*, *XMLType_view_clause*, or BEQUEATH clause.
- You cannot define a constraint WITH CHECK OPTION on an editioning view.
- In the select list of the defining subquery, you can specify only simple references to the columns of the base table, and you can specify each column of the base table only once in the select list. The asterisk wildcard symbol * and *t_alias.** are supported to designate all columns of a base table.
- The FROM clause of the defining subquery of the view can reference only a single existing database table. Joins are not permitted. The base table must be in the same schema as the view being created. You cannot use a synonym to identify the table, but you can specify a table alias.
- The following clauses of the defining subquery are not valid for editioning views: *subquery_factoring_clause*, DISTINCT or UNIQUE, *where_clause*, *hierarchical_query_clause*, *group_by_clause*, HAVING condition, *model_clause*, or the set operators (UNION, INTERSECT, or MINUS)

① See Also

- *Oracle AI Database Development Guide* for detailed information about editioning views
- [CREATE EDITION](#) for information about editions, including an example of an editioning view

EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is enabled for the schema object type VIEW in *schema*. The default is EDITIONABLE. For information about editioned and noneditioned objects, see *Oracle AI Database Development Guide*.

JSON Collection

You can create a JSON COLLECTION view that maps JSON documents to underlying relational data.

A JSON COLLECTION view is a special view that provides JSON documents in a single JSON-type object column named DATA. You cannot specify more than one column, otherwise you will raise an error.

JSON COLLECTION views are read only.

It is recommended, but not mandatory to define an `_id` column pointing to the unique identifier of the view to follow the standard format of JSON collections in Oracle.

Example

```
CREATE OR REPLACE JSON COLLECTION VIEW  
AS  
SELECT JSON { '_id': deptno, 'deptName': dname } DATA  
FROM dept ;
```

For more information on JSON relational duality views, fully updateable views on top of relational tables, see [CREATE JSON RELATIONAL DUALITY VIEW](#).

For more on JSON collections, see JSON Collections of the *JSON Developer's Guide*.

IF NOT EXISTS

Specifying IF NOT EXISTS has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of OR REPLACE or IF NOT EXISTS in a statement at a time. Using both OR REPLACE with IF NOT EXISTS in the very same statement results in the following error:
ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

schema

Specify the schema to contain the view. If you omit *schema*, then the database creates the view in your own schema.

view

Specify the name of the view or the object view. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

Restriction on Views

If a view has INSTEAD OF triggers, then any views created on it must have INSTEAD OF triggers, even if the views are inherently updatable.

① See Also

["Creating a View: Example"](#)

SHARING

This clause applies only when creating a view in an application root. This type of view is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the view data is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the view's metadata, but its data is unique to each container. This type of view is referred to as a **metadata-linked application common object**.
- **DATA** - A data link shares the view, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of view is referred to as a **data-linked application common object**.
- **EXTENDED DATA** - An extended data link shares the view, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of view, data is stored in the application root and, optionally, in each application PDB. This type of view is referred to as an **extended data-linked application common object**.
- **NONE** - The view is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the view. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

When creating a conventional view, you can specify `METADATA`, `DATA`, `EXTENDED DATA`, or `NONE`.

When creating an object view or an `XMLTYPE` view, you can specify only `METADATA` or `NONE`.

You cannot change the sharing attribute of a view after it is created.

① See Also

- *Oracle AI Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle AI Database Administrator's Guide* for complete information on creating application common objects

alias

Specify names for the expressions selected by the defining query of the view. The number of aliases must match the number of expressions selected by the view. Aliases must follow the rules for naming the database schema objects. Aliases must be unique within the view.

If you omit the aliases, then the database derives them from the columns or column aliases in the query. For this reason, you must use aliases if the query contains expressions rather than only column names. Also, you must specify aliases if the view definition includes constraints and/or column annotations.

Restriction on View Aliases

You cannot specify an alias when creating an object view.

① See Also

["Syntax for Schema Objects and Parts in SQL Statements"](#)

VISIBLE | INVISIBLE

Use this clause to specify whether a view column is `VISIBLE` or `INVISIBLE`. By default, view columns are `VISIBLE` regardless of their visibility in the base tables, unless you specify `INVISIBLE`. This applies to conventional views and editioning views. For complete information on these clauses, refer to "[VISIBLE | INVISIBLE](#)" in the documentation on `CREATE TABLE`.

inline_constraint* and *out_of_line_constraint

You can specify constraints on views and object views. You define the constraint at the view level using the *out_of_line_constraint* clause. You define the constraint as part of column or attribute specification using the *inline_constraint* clause after the appropriate alias.

The database does not enforce view constraints. For a full discussion of view constraints, including restrictions, refer to "[View Constraints](#)".

① See Also

["Creating a View with Constraints: Example"](#)

object_view_clause

The *object_view_clause* lets you define a view on an object type.

① See Also

["Creating an Object View: Example"](#)

OF *type_name* Clause

Use this clause to explicitly create an **object view** of type *type_name*. The columns of an object view correspond to the top-level attributes of type *type_name*. Each row will contain an object instance and each instance will be associated with an object identifier as specified in the WITH OBJECT IDENTIFIER clause. If you omit *schema*, then the database creates the object view in your own schema.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, the database defines a system-generated pseudocolumn OBJECT_ID. You can use this column name in queries and to create object views with the WITH OBJECT IDENTIFIER clause.

WITH OBJECT IDENTIFIER Clause

Use the WITH OBJECT IDENTIFIER clause to specify a top-level (root) object view. This clause lets you specify the attributes of the object type that will be used as a key to identify each row in the object view. In most cases these attributes correspond to the primary key columns of the base table. You must ensure that the attribute list is unique and identifies exactly one row in the view. The WITH OBJECT IDENTIFIER and WITH OBJECT ID clauses can be used interchangeably and are provided for semantic clarity.

Restrictions on Object Views

Object views are subject to the following restrictions:

- If you try to dereference or pin a primary key REF that resolves to more than one instance in the object view, then the database returns an error.
- You cannot specify this clause if you are creating a subview, because subviews inherit object identifiers from superviews.

If the object view is defined on an object table or an object view, then you can omit this clause or specify DEFAULT.

DEFAULT

Specify DEFAULT if you want the database to use the intrinsic object identifier of the underlying object table or object view to uniquely identify each row.

attribute

For *attribute*, specify an attribute of the object type from which the database should create the object identifier for the object view.

UNDER Clause

Use the UNDER clause to specify a subview based on an object superview.

Restrictions on Subviews

Subviews are subject to the following restrictions:

- You must create a subview in the same schema as the superview.
- The object type *type_name* must be the immediate subtype of *superview*.

- You can create only one subview of a particular type under the same superview.

① See Also

- [CREATE TYPE](#) for information about creating objects
- *Oracle AI Database Reference* for information on data dictionary views

XMLType_view_clause

Use this clause to create an XMLType view, which displays data from an XMLSchema-based table of type XMLType. The *XMLSchema_spec* indicates the XMLSchema to be used to map the XML data to its object-relational equivalents. The XMLSchema must already have been created before you can create an XMLType view.

The WITH OBJECT IDENTIFIER and WITH OBJECT ID clauses can be used interchangeably and are provided for semantic clarity.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, the database defines a system-generated pseudocolumn OBJECT_ID. You can use this column name in queries and to create object views with the WITH OBJECT IDENTIFIER clause.

① See Also

- *Oracle XML DB Developer's Guide* for information on XMLType views and XMLSchemas
- "[Creating an XMLType View: Example](#)" and "[Creating a View on an XMLType Table: Example](#)"

annotations_clause

For the full semantics of the annotations clause see [annotations_clause](#).

DEFAULT COLLATION

Use this clause to specify the default collation for the view. The default collation is used as the derived collation for all the character literals included in the defining query of the view. The default collation is not used by the view columns; the collations for the view columns are derived from the view's defining subquery. The CREATE VIEW statement fails with an error if any of its character columns is based on an expression in the defining subquery that has no derived collation.

For *collation_name*, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the view is set to the effective schema default collation of the schema containing the view. Refer to the [DEFAULT COLLATION](#) clause of ALTER SESSION for more information on the effective schema default collation.

You can specify the DEFAULT COLLATION clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX_STRING_SIZE initialization parameter is set to EXTENDED.

To change the default collation for a view, you must recreate the view.

Restriction on the Default Collation for Views

If the defining query of the view contains the `WITH plsql_declarations` clause, then the default collation of the view must be `USING_NLS_COMP`.

BEQUEATH

Use the `BEQUEATH` clause to specify whether functions referenced in the view are executed using the view invoker's rights or the view definer's rights.

CURRENT_USER

If you specify `BEQUEATH CURRENT_USER`, then functions referenced by the view are executed using the view invoker's rights as long as one of the following conditions is met:

- The view owner has the `INHERIT PRIVILEGES` object privilege on the invoking user.
- The view owner has the `INHERIT ANY PRIVILEGES` system privilege.

If a query of the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the querying user's environment, rather than from the owner of the view.

This clause does not turn the view itself into an invoker's rights object. Name resolution within the view is still handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

DEFINER

If you specify `BEQUEATH DEFINER`, then functions referenced by the view are executed using the view definer's rights. If a query on the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the owner of the view.

Name resolution within the view is handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

This is the default.

Restriction on the BEQUEATH Clause

You cannot specify this clause with the `EDITIONING` clause.

See Also

Oracle AI Database Security Guide for more information on controlling invoker's rights and definer's rights in views

AS subquery

Specify a subquery that identifies columns and rows of the table(s) that the view is based on. The select list of the subquery can contain up to 1000 expressions.

If you create views that refer to remote tables and views, then the database links you specify must have been created using the `CONNECT TO` clause of the `CREATE DATABASE LINK` statement, and you must qualify them with a schema name in the view subquery.

If you create a view with the *flashback_query_clause* in the defining query, then the database does not interpret the AS OF expression at create time but rather each time a user subsequently queries the view.

See Also

"[Creating a Join View: Example](#)" and *Oracle AI Database Development Guide* for more information on Oracle Flashback Query

Restrictions on the Defining Query of a View

The view query is subject to the following restrictions:

- The subquery cannot select the CURRVAL or NEXTVAL pseudocolumns.
- If the subquery selects the ROWID, ROWNUM, or LEVEL pseudocolumns, then those columns must have aliases in the view subquery.
- If the subquery uses an asterisk (*) to select all columns of a table, and you later add new columns to the table, then the view will not contain those columns until you re-create the view by issuing a CREATE OR REPLACE VIEW statement.
- For object views, the number of elements in the subquery select list must be the same as the number of top-level attributes for the object type. The data type of each of the selecting elements must be the same as the corresponding top-level attribute.
- You cannot specify the SAMPLE clause.

The preceding restrictions apply to materialized views as well.

Notes on Updatable Views

The following notes apply to updatable views:

An updatable view is one you can use to insert, update, or delete base table rows. You can create a view to be inherently updatable, or you can create an INSTEAD OF trigger on any view to make it updatable.

To learn whether and in what ways the columns of an inherently updatable view can be modified, query the USER_UPDATABLE_COLUMNS data dictionary view. The information displayed by this view is meaningful only for inherently updatable views. For a view to be inherently updatable, the following conditions must be met:

- Each column in the view must map to a column of a single table. For example, if a view column maps to the output of a TABLE clause (an unnested collection), then the view is not inherently updatable.
- The view must not contain any of the following constructs:
 - A set operator
 - A DISTINCT operator
 - An aggregate or analytic function
 - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
 - A collection expression in a SELECT list
 - A subquery in a SELECT list
 - A subquery designated WITH READ ONLY
 - Joins, with some exceptions, as documented in *Oracle AI Database Administrator's Guide*

- In addition, if an inherently updatable view contains pseudocolumns or expressions, then you cannot update base table rows with an UPDATE statement that refers to any of these pseudocolumns or expressions.
- If you want a join view to be updatable, then all of the following conditions must be true:
 - The DML statement must affect only one table underlying the join.
 - For an INSERT statement, the view must not be created WITH CHECK OPTION, and all columns into which values are inserted must come from a **key-preserved table**. A key-preserved table is one for which every primary key or unique key value in the base table is also unique in the join view.
 - For an UPDATE statement, the view must not be created WITH CHECK OPTION, and update must be deterministic (updates each row only once).
 - For a DELETE statement, if the join results in more than one key-preserved table, then the database deletes from the first table named in the FROM clause, whether or not the view was created WITH CHECK OPTION.

📘 See Also

- *Oracle AI Database Administrator's Guide* for more information on updatable views
- "[Creating an Updatable View: Example](#)", "[Creating a Join View: Example](#)" for an example of updatable join views and key-preserved tables, and *Oracle AI Database PL/SQL Language Reference* for an example of an INSTEAD OF trigger on a view that is not inherently updatable

subquery_restriction_clause

Use the *subquery_restriction_clause* to restrict the defining query of the view in one of the following ways:

WITH READ ONLY

Specify WITH READ ONLY to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify WITH CHECK OPTION to indicate that the database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

CONSTRAINT *constraint*

Specify the name of the READ ONLY or CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS_Cn, where *n* is an integer that makes the constraint name unique within the database.

Note

For tables, WITH CHECK OPTION guarantees that inserts and updates result in tables that the defining table subquery can select. For views, WITH CHECK OPTION cannot make this guarantee if:

- There is a subquery within the defining query of this view or any view on which this view is based or
- INSERT, UPDATE, or DELETE operations are performed using INSTEAD OF triggers.

Restriction on the *subquery_restriction_clause*

You cannot specify this clause if you specify an ORDER BY clause.

See Also

["Creating a Read-Only View: Example"](#)

CONTAINER_MAP

Specify the CONTAINER_MAP clause to enable the view to be queried using a container map.

CONTAINERS_DEFAULT

Specify the CONTAINERS_DEFAULT clause to enable the view for the CONTAINERS clause.

Examples**Creating a View: Example**

The following statement creates a view of the sample table employees named emp_view. The view shows the employees in department 20 and their annual salary:

```
CREATE VIEW emp_view AS
  SELECT last_name, salary*12 annual_salary
  FROM employees
  WHERE department_id = 20;
```

The view declaration need not define a name for the column based on the expression salary*12, because the subquery uses a column alias (annual_salary) for this expression.

Creating an Editioning View: Example

The following statement creates an editioning view of the orders table:

```
CREATE EDITIONING VIEW ed_orders_view (o_id, o_date, o_status)
  AS SELECT order_id, order_date, order_status FROM orders
  WITH READ ONLY;
```

You can use this view to isolate an application from DDL changes to the orders table during an administrative operation such as an upgrade. You can create a DML trigger on this view, so that the trigger fires when a DML operation targets the view itself, but does not fire if the DML operation targets the orders table.

Creating a View with Constraints: Example

The following statement creates a restricted view of the sample table `hr.employees` and defines a unique constraint on the `email` view column and a primary key constraint for the view on the `emp_id` view column:

```
CREATE VIEW emp_sal (emp_id, last_name,
                    email UNIQUE RELY DISABLE NOVALIDATE,
                    CONSTRAINT id_pk PRIMARY KEY (emp_id) RELY DISABLE NOVALIDATE)
AS SELECT employee_id, last_name, email FROM employees;
```

Creating an Updatable View: Example

The following statement creates an updatable view named `clerk` of all clerks in the `employees` table. Only the employees' IDs, last names, department numbers, and jobs are visible in this view, and these columns can be updated only in rows where the employee is a kind of clerk:

```
CREATE VIEW clerk AS
SELECT employee_id, last_name, department_id, job_id
FROM employees
WHERE job_id = 'PU_CLERK'
   or job_id = 'SH_CLERK'
   or job_id = 'ST_CLERK';
```

This view lets you change the `job_id` of a purchasing clerk to purchasing manager (`PU_MAN`):

```
UPDATE clerk SET job_id = 'PU_MAN' WHERE employee_id = 118;
```

The next example creates the same view `WITH CHECK OPTION`. You cannot subsequently insert a new row into `clerk` if the new employee is not a clerk. You can update an employee's `job_id` from one type of clerk to another type of clerk, but the update in the preceding statement would fail, because the view cannot access employees with non-clerk `job_id`.

```
CREATE VIEW clerk AS
SELECT employee_id, last_name, department_id, job_id
FROM employees
WHERE job_id = 'PU_CLERK'
   or job_id = 'SH_CLERK'
   or job_id = 'ST_CLERK'
WITH CHECK OPTION;
```

Creating a Join View: Example

A join view is one whose view subquery contains a join. If at least one column in the join has a unique index, then it may be possible to modify one base table in a join view. You can query `USER_UPDATABLE_COLUMNS` to see whether the columns in a join view are updatable. For example:

```
CREATE VIEW locations_view AS
SELECT d.department_id, d.department_name, l.location_id, l.city
FROM departments d, locations l
WHERE d.location_id = l.location_id;

SELECT column_name, updatable
FROM user_updatable_columns
WHERE table_name = 'LOCATIONS_VIEW'
ORDER BY column_name, updatable;
```

COLUMN_NAME	UPD
-----	---
DEPARTMENT_ID	YES
DEPARTMENT_NAME	YES
LOCATION_ID	NO
CITY	NO

In the preceding example, the primary key index on the `location_id` column of the `locations` table is not unique in the `locations_view` view. Therefore, `locations` is not a key-preserved table and columns from that base table are not updatable.

```
INSERT INTO locations_view VALUES
  (999, 'Entertainment', 87, 'Roma');
INSERT INTO locations_view VALUES
  *
ERROR at line 1:
ORA-01776: cannot modify more than one base table through a join view
```

You can insert, update, or delete a row from the `departments` base table, because all the columns in the view mapping to the `departments` table are marked as updatable and because the primary key of `departments` is retained in the view.

```
INSERT INTO locations_view (department_id, department_name)
  VALUES (999, 'Entertainment');
```

1 row created.

Note

For you to insert into the table using the view, the view must contain all NOT NULL columns of all tables in the join, unless you have specified DEFAULT values for the NOT NULL columns.

See Also

Oracle AI Database Administrator's Guide for more information on updating join views

Creating a Read-Only View: Example

The following statement creates a read-only view named `customer_ro` of the `oe.customers` table. Only the customers' last names, language, and credit limit are visible in this view:

```
CREATE VIEW customer_ro (name, language, credit)
  AS SELECT cust_last_name, nls_language, credit_limit
  FROM customers
  WITH READ ONLY;
```

Creating an Object View: Example

The following example shows the creation of the type `inventory_typ` in the `oc` schema, and the `oc_inventories` view that is based on that type:

```
CREATE TYPE inventory_typ
  OID '82A4AF6A4CD4656DE034080020E0EE3D'
  AS OBJECT
    ( product_id      NUMBER(6)
    , warehouse      warehouse_typ
    , quantity_on_hand NUMBER(8)
    ) ;
/
CREATE OR REPLACE VIEW oc_inventories OF inventory_typ
  WITH OBJECT OID (product_id)
  AS SELECT i.product_id,
```

```

        warehouse_typ(w.warehouse_id, w.warehouse_name, w.location_id),
        i.quantity_on_hand
    FROM inventories i, warehouses w
    WHERE i.warehouse_id=w.warehouse_id;

```

Creating a View on an XMLType Table: Example

The following example builds a regular view on the XMLType table xwarehouses, which was created in ["Examples"](#):

```

CREATE VIEW warehouse_view AS
    SELECT VALUE(p) AS warehouse_xml
    FROM xwarehouses p;

```

You select from such a view as follows:

```

SELECT e.warehouse_xml.getclobval()
    FROM warehouse_view e
    WHERE EXISTSNode(warehouse_xml, '//Docks') =1;

```

Creating an XMLType View: Example

In some cases you may have an object-relational table upon which you would like to build an XMLType view. The following example creates an object-relational table resembling the XMLType column warehouse_spec in the sample table oe.warehouses, and then creates an XMLType view of that table:

```

CREATE TABLE warehouse_table
(
    WarehouseID      NUMBER,
    Area              NUMBER,
    Docks              NUMBER,
    DockType           VARCHAR2(100),
    WaterAccess        VARCHAR2(10),
    RailAccess         VARCHAR2(10),
    Parking            VARCHAR2(20),
    VClearance         NUMBER
);

INSERT INTO warehouse_table
    VALUES(5, 103000,3,'Side Load','false','true','Lot',15);

CREATE VIEW warehouse_view OF XMLTYPE
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse"
    WITH OBJECT ID
        (extract(OBJECT_VALUE, '/Warehouse/Area/text()').getnumberval())
    AS SELECT XMLELEMENT("Warehouse",
        XMLFOREST(WarehouseID as "Building",
            area as "Area",
            docks as "Docks",
            docktype as "DockType",
            wateraccess as "WaterAccess",
            railaccess as "RailAccess",
            parking as "Parking",
            VClearance as "VClearance"))
    FROM warehouse_table;

```

You query this view as follows:

```

SELECT VALUE(e) FROM warehouse_view e;

```

Creating a View with Column and View Level Annotations: Example

```
CREATE OR REPLACE VIEW high_wage_employees (  
  employee_id ANNOTATIONS (identity, display 'Employee ID'),  
  first_name ANNOTATIONS (display 'Employee Name'),  
  salary ANNOTATIONS (display 'Emp Salary') )  
ANNOTATIONS (Title 'High Wage Employee View') AS  
SELECT employee_id, first_name, salary  
FROM employees  
WHERE salary > 100000;
```

DELETE

Purpose

Use the DELETE statement to remove rows from:

- An unpartitioned or partitioned table
- The unpartitioned or partitioned base table of a view
- The unpartitioned or partitioned container table of a writable materialized view
- The unpartitioned or partitioned master table of an updatable materialized view

Prerequisites

For you to delete rows from a table, the table must be in your own schema or you must have the DELETE object privilege on the table.

For you to delete rows from an updatable materialized view, the materialized view must be in your own schema or you must have the DELETE object privilege on the materialized view.

For you to delete rows from the base table of a view, the owner of the schema containing the view must have the DELETE object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the DELETE object privilege on the view.

The DELETE ANY TABLE system privilege also allows you to delete rows from any table or table partition or from the base table of any view.

To delete rows from an object on a remote database, you must also have the READ or SELECT object privilege on the object.

To specify the *returning_clause*, you must have the READ or SELECT object privilege on the object.

If the SQL92_SECURITY initialization parameter is set to TRUE and the DELETE operation references table columns, such as the columns in a *where_clause* or *returning_clause*, then you must have the SELECT object privilege on the object from which you want to delete rows.

You cannot delete rows from a table if a function-based index on the table has become invalid. You must first validate the function-based index.

[*\(partition_extension_clause::=, subquery::=, subquery_restriction_clause::=, table_collection_expression::=\)*](#)

partition_extension_clause::=

subquery_restriction_clause::=

table_collection_expression::=

from_using_clause::=

where_clause::=

wait_clause

returning_clause::=

error_logging_clause::=**Semantics*****hint***

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

See Also

"[Hints](#)" for the syntax and description of hints

from_clause

Use the FROM clause to specify the database objects from which you are deleting rows.

The ONLY syntax is relevant only for views. Use the ONLY clause if the view in the FROM clause belongs to a view hierarchy and you do not want to delete rows from any of its subviews.

DML_table_expression_clause

Use this clause to specify the objects from which data is being deleted.

schema

Specify the schema containing the table or view. If you omit *schema*, then the database assumes the table or view is in your own schema.

table | view | materialized view | subquery

Specify the name of a table, view, materialized view, or the column or columns resulting from a subquery, from which the rows are to be deleted.

When you delete rows from an updatable view, the database deletes rows from the base table.

You cannot delete rows from a read-only materialized view. If you delete rows from a writable materialized view, then the database removes the rows from the underlying container table. However, the deletions are overwritten at the next refresh operation. If you delete rows from an updatable materialized view that is part of a materialized view group, then the database also removes the corresponding rows from the master table.

If *table* or the base table of *view* or the master table of *materialized view* contains one or more domain index columns, then this statement executes the appropriate indextype delete routine.

① See Also

Oracle AI Database Data Cartridge Developer's Guide for more information on these routines

Issuing a DELETE statement against a table fires any DELETE triggers defined on the table.

All table or index space released by the deleted rows is retained by the table and index.

partition_extension_clause

Specify the name or partition key value of the partition or subpartition targeted for deletes within the object.

You need not specify the partition name when deleting values from a partitioned object. However, in some cases, specifying the partition name is more efficient than a complicated *where_clause*.

① See Also

"[References to Partitioned Tables and Indexes](#)" and "[Deleting Rows from a Partition: Example](#)"

dblink

Specify the complete or partial name of a database link to a remote database where the object is located. You can delete rows from a remote object only if you are using the database distributed functionality.

① Note

Starting with Oracle Database 12c Release 2 (12.2), the DELETE statement accepts remote LOB locators as bind variables. Refer to the "Distributed LOBs" chapter in *Oracle AI Database SecureFiles and Large Objects Developer's Guide* for more information.

① See Also

"[References to Objects in Remote Databases](#)" for information on referring to database links and "[Deleting Rows from a Remote Database: Example](#)"

If you omit *dblink*, then the database assumes that the object is located on the local database.

subquery_restriction_clause

The *subquery_restriction_clause* lets you restrict the subquery in one of the following ways:

WITH READ ONLY

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify `WITH CHECK OPTION` to indicate that the database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

CONSTRAINT *constraint*

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

① See Also

["Using the WITH CHECK OPTION Clause: Example"](#)

table_collection_expression

The *table_collection_expression* lets you inform Oracle that the value of *collection_expression* should be treated as a table for purposes of query and DML operations. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

① Note

In earlier releases of Oracle, when *collection_expression* was a subquery, *table_collection_expression* was expressed as `THE subquery`. That usage is now deprecated.

You can use a *table_collection_expression* in a correlated subquery to delete rows with values that also exist in another table.

① See Also

["Table Collections: Examples"](#)

collection_expression

Specify a subquery that selects a nested table column from the object from which you are deleting.

Restrictions on the *dml_table_expression_clause* Clause

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base or master table of *view* or *materialized_view* contains any domain indexes marked IN_PROGRESS or FAILED.
- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.
- You cannot specify the ORDER BY clause in the subquery of the *DML_table_expression_clause*.
- You cannot delete from a view except through INSTEAD OF triggers if the defining query of the view contains one of the following constructs:
 - A set operator
 - A DISTINCT operator
 - An aggregate or analytic function
 - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
 - A collection expression in a SELECT list
 - A subquery in a SELECT list
 - A subquery designated WITH READ ONLY
 - Joins, with some exceptions, as documented in *Oracle AI Database Administrator's Guide*

If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the DELETE statement will fail unless the SKIP_UNUSABLE_INDEXES initialization parameter has been set to true.

① **See Also**

[ALTER SESSION](#)

t_alias

Provide a **correlation name** for the table, view, materialized view, subquery, or collection value to be referenced elsewhere in the statement. This alias is required if the *DML_table_expression_clause* references any object type attributes or object type methods. Table aliases are generally used in DELETE statements with correlated queries.

from_using_clause

Use this clause to filter the rows DELETE removes. Specify the join conditions in the *where_clause*. You can outer join source tables to the target with (+). The target table cannot be the outer table in the join.

You can join many tables, views, and inline views. Specify the join conditions in the *where_clause* or use the *join_clause* to join these to each other with ANSI join syntax.

You can specify the same table in the *dml_table_expression_clause* and *from_using_clause*. When you do so they must have unique aliases.

Example: Delete with Direct-Join

In this example, the join condition between table *t* and table *s* determines which rows of *t* are deleted:

```
DELETE FROM t
FROM s
WHERE t.t1 = s.s1;
```

If the join condition results in the same target row being selected more than once, the DELETE will succeed, and the deletion count will correctly reflect the number of rows deleted.

In a DELETE of a join view, one of the tables must be key-preserving. That table is used as the delete target. If there is more than one table that is key-preserving, the first key-preserved table encountered in the FROM clause is used as the delete target. If no such table exists, error ORA-01752 is raised. There is no such restriction in direct join syntax, since it is clear what the delete target is.

Direct joins for DELETE have the same semantics and restrictions as SELECT in the *from_clause* and *where_clause*. Triggers on the target table fire as normal.

Restrictions

- You cannot specify ANSI join syntax using the *dml_table_expression_clause*. However, you can specify ANSI join syntax between the tables specified in the FROM clause. Right and full outer joins are not allowed.
- You can use a lateral view in the FROM clause, but it cannot reference a column from the delete target. It may be outer-joined.
- You can only specify one table, view, or materialized view in *dml_table_expression_clause* when the *from_using_clause* is present.
- The *hint* clause can be used to specify instructions to the optimizer for joins involving the *from_using_clause*

where_clause

Use the *where_clause* to delete only rows that satisfy the condition. The condition can reference the object from which you are deleting and can contain a subquery. You can delete rows from a remote object only if you are using the database distributed functionality. Refer to [Conditions](#) for the syntax of *condition*.

If this clause contains a *subquery* that refers to remote objects, then the DELETE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the *subquery* in the *DML_table_expression_clause* refers to any remote objects, then the DELETE operation will run serially without notification. Refer to the [parallel_clause](#) in the CREATE TABLE documentation for additional information.

If you omit *dblink*, then the database assumes that the table or view is located on the local database.

If you omit the *where_clause*, then the database deletes all rows of the object.

wait_clause

The NOWAIT and WAIT clauses let you tell the database how to proceed if a transaction attempts to lock a row that is locked by another transaction.

Specify NOWAIT to rollback the DML statement immediately, if a lock exists.

Specify WAIT to instruct the database to wait *integer* SECONDS, MILLISECONDS, or MICROSECONDS. Seconds is the default.

Specify WAIT FOREVER to instruct the database to retain its default behavior of waiting for row locks indefinitely.

If you specify neither WAIT nor NOWAIT, then the database retains its default behavior of waiting for row locks indefinitely.

returning_clause

This clause lets you return values from deleted columns, and thereby eliminate the need to issue a SELECT statement following the DELETE statement.

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a *returning_clause* can retrieve column expressions using the affected row, rowid, and REFS to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning_clause* stores values from expressions, rowids, and REFS involving the affected rows in bind arrays.

expr

Each item in the *expr* list must be a valid expression syntax.

INTO

The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data_item* list.

data_item

Each *data_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

Restrictions on the RETURNING Clause

The following restrictions apply to the RETURNING clause:

- The *expr* is restricted as follows:
 - For UPDATE and DELETE statements each *expr* must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same *returning_clause*. For INSERT statements, each *expr* must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
 - Single-set aggregate function expressions cannot include the DISTINCT keyword.
- If the *expr* list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the *returning_clause* for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve LONG types with this clause.
- You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

See Also

- *Oracle AI Database PL/SQL Language Reference* for information on using the BULK COLLECT clause to return multiple values to collection variables
- ["Using the RETURNING Clause: Example"](#)

error_logging_clause

The *error_logging_clause* has the same behavior in DELETE statement as it does in an INSERT statement. Refer to the INSERT statement [error_logging_clause](#) for more information.

See Also

["Inserting Into a Table with Error Logging: Example"](#)

Examples**Deleting Rows: Examples**

The following statement deletes all rows from the sample table `oe.product_descriptions` where the value of the `language_id` column is AR:

```
DELETE FROM product_descriptions
WHERE language_id = 'AR';
```

The following statement deletes from the sample table `hr.employees` purchasing clerks whose commission rate is less than 10%:

```
DELETE FROM employees
WHERE job_id = 'SA_REP'
AND commission_pct < .2;
```

The following statement has the same effect as the preceding example, but uses a subquery:

```
DELETE FROM (SELECT * FROM employees)
WHERE job_id = 'SA_REP'
AND commission_pct < .2;
```

Deleting Rows from a Remote Database: Example

The following statement deletes specified rows from the `locations` table owned by the user `hr` on a database accessible by the database link `remote`:

```
DELETE FROM hr.locations@remote
WHERE location_id > 3000;
```

Deleting Nested Table Rows: Example

For an example that deletes nested table rows, refer to ["Table Collections: Examples"](#).

Deleting Rows from a Partition: Example

The following example removes rows from partition `sales_q1_1998` of the `sh.sales` table:

```
DELETE FROM sales PARTITION (sales_q1_1998)
WHERE amount_sold > 1000;
```

Using the RETURNING Clause: Example

The following example returns column salary from the deleted rows and stores the result in bind variable :bnd1. The bind variable must already have been declared.

```
DELETE FROM employees
  WHERE job_id = 'SA_REP'
     AND hire_date + TO_YMINTERVAL('01-00') < SYSDATE
     RETURNING salary INTO :bnd1;
```

Deleting Data from a Table: Example

The following statements create a table named product_price_history and insert data into it:

```
CREATE TABLE product_price_history (
  product_id          INTEGER NOT NULL,
  price               INTEGER NOT NULL,
  currency_code       VARCHAR2(3 CHAR) NOT NULL,
  effective_from_date DATE NOT NULL,
  effective_to_date   DATE,
  CONSTRAINT product_price_history_pk
    PRIMARY KEY (product_id, currency_code, effective_from_date)
) PARTITION BY RANGE (effective_from_date) (
  PARTITION p0 VALUES less than (DATE'2015-01-02'),
  PARTITION p1 VALUES less than (DATE'2015-01-03'),
  PARTITION p2 VALUES less than (DATE'2015-01-04')
);

INSERT INTO product_price_history
  WITH prices AS (
    SELECT 1, 100, 'USD', DATE'2015-01-01', DATE'2015-01-02'
    FROM   dual UNION ALL
    SELECT 1, 60, 'GBP', DATE'2015-01-01', DATE'2015-01-02'
    FROM   dual UNION ALL
    SELECT 1, 110, 'EUR', DATE'2015-01-01', DATE'2015-01-02'
    FROM   dual UNION ALL
    SELECT 1, 101, 'USD', DATE'2015-01-02', DATE'2015-01-03'
    FROM   dual UNION ALL
    SELECT 1, 62, 'GBP', DATE'2015-01-02', DATE'2015-01-03'
    FROM   dual UNION ALL
    SELECT 1, 109, 'EUR', DATE'2015-01-02', DATE'2015-01-03'
    FROM   dual UNION ALL
    SELECT 1, 105, 'USD', DATE'2015-01-03', NULL
    FROM   dual UNION ALL
    SELECT 1, 61, 'GBP', DATE'2015-01-03', NULL
    FROM   dual UNION ALL
    SELECT 1, 107, 'EUR', DATE'2015-01-03', NULL
    FROM   dual UNION ALL
    SELECT 2, 30, 'USD', DATE'2015-01-01', DATE'2015-01-03'
    FROM   dual UNION ALL
    SELECT 2, 33, 'USD', DATE'2015-01-03', NULL
    FROM   dual UNION ALL
    SELECT 3, 100, 'GBP', DATE'2015-01-03', NULL
    FROM   dual
  )
  SELECT *
  FROM   prices;
```

The following statement deletes the rows from the table product_price_history where product_id is 3:

```
DELETE FROM product_price_history WHERE product_id = 3;
```

The following procedure deletes the rows from the product_price_history where product_id is 2 and effective_to_date is NULL:

```
DECLARE
    currency product_price_history.currency_code%TYPE;
BEGIN
    DELETE product_price_history
    WHERE product_id = 2
    AND    effective_to_date IS NULL
    returning currency_code INTO currency;

    dbms_output.Put_line(currency);
END;

USD
```

The following statement deletes the rows from the table product_price_history where currency_code is 'EUR':

```
DELETE (SELECT * FROM product_price_history) WHERE currency_code = 'EUR';
```

The following statement uses a subquery to delete rows from product_price_history:

```
DELETE product_price_history pp
WHERE (product_id, currency_code, effective_from_date)
      IN (SELECT product_id, currency_code, Max(effective_from_date)
          FROM   product_price_history
          GROUP BY product_id, currency_code);
```

The following statement uses partitions to delete rows from product_price_history:

```
DELETE product_price_history partition (p1);
```

The following statement displays the table information:

```
SELECT * FROM product_price_history;
```

PRODUCT_ID	PRICE	CUR	EFFECTIVE	EFFECTIVE
1	100	USD	01-JAN-15	02-JAN-15
1	60	GBP	01-JAN-15	02-JAN-15

The following statement deletes all rows from product_price_history:

```
DELETE product_price_history;
```

Delete Using Wait: Example

Note: AUTOCOMMIT is OFF.

Fork 2 sessions and run the commands alternatively in each as follows:

Session 1:

```
DELETE FROM employees WHERE employee_id = 104;
1 row deleted.
```

Session 2:

```
DELETE FROM employees WHERE employee_id = 104 WAIT 10;
```

The statement fails after waiting 10 seconds. Error messages:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",
Description: "Lock held by a transaction to allow other transactions to wait
for it") because it is currently held by another session. The resource being
locked can be identified by 655371 ("usn<<16 | slot") and 1177 ("sequence")
ORA-40097: Failure to acquire row lock, currently held by transaction ID 10.11.1177
```

Session 1:

```
ROLLBACK;
Rollback complete.
SELECT employee_id, first_name, last_name FROM employees WHERE employee_id
= 104;
EMPLOYEE_ID FIRST_NAME          LAST_NAME
-----
104          Bruce              Ernst
```

Session 2:

```
SELECT employee_id, first_name, last_name FROM employees WHERE employee_id =
104;
EMPLOYEE_ID FIRST_NAME          LAST_NAME
-----
104          Bruce              Ernst
```

Delete Using NOWAIT: Example

Session 1:

```
DELETE FROM employees WHERE employee_id = 104;
1 row deleted.
```

Session 2:

```
DELETE FROM employees WHERE employee_id = 104 NOWAIT;
```

The statement fails immediately on detecting a row lock. The following error messages appear:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",
Description: "Lock held by a transaction to allow other transactions to wait
for it") because it is currently held by another session. The resource being
locked can be identified by 655371 ("usn<<16 | slot") and 1177 ("sequence")
ORA-40097: Failure to acquire row lock, currently held by transaction ID 10.11.1177
```

Session 1:

```
ROLLBACK;
Rollback complete.
```

DISASSOCIATE STATISTICS

Purpose

Use the `DISASSOCIATE STATISTICS` statement to disassociate default statistics or a statistics type from columns, standalone functions, packages, types, domain indexes, or indextypes.

See Also

[ASSOCIATE STATISTICS](#) for more information on statistics type associations

Prerequisites

To issue this statement, you must have the appropriate privileges to alter the underlying table, function, package, type, domain index, or indextype.

Syntax

`disassociate_statistics::=`

Semantics

FROM COLUMNS | FUNCTIONS | PACKAGES | TYPES | INDEXES | INDEXTYPES

Specify one or more columns, standalone functions, packages, types, domain indexes, or indextypes from which you are disassociating statistics.

If you do not specify *schema*, then Oracle Database assumes the object is in your own schema.

If you have collected user-defined statistics on the object, then the statement fails unless you specify **FORCE**.

FORCE

Specify **FORCE** to remove the association regardless of whether any statistics exist for the object using the statistics type. If statistics do exist, then the statistics are deleted before the association is deleted.

Note

When you drop an object with which a statistics type has been associated, Oracle Database automatically disassociates the statistics type with the **FORCE** option and drops all statistics that have been collected with the statistics type.

Examples

Disassociating Statistics: Example

This statement disassociates statistics from the `emp_mgmt` package. See *Oracle Database PL/SQL Language Reference* for the example that creates this package in the `hr` schema.

```
DISASSOCIATE STATISTICS FROM PACKAGES hr.emp_mgmt;
```

DROP ANALYTIC VIEW

Purpose

Use the **DROP ANALYTIC VIEW** statement to drop an analytic view. An **ANALYTIC VIEW** object is a component of analytic views.

Prerequisites

To drop an analytic view in your own schema, you must have the **DROP ANALYTIC VIEW** system privilege. To drop an analytic view in another user's schema, you must have the **DROP ANY ANALYTIC VIEW** system privilege.

Syntax

drop_analytic_view::=

Semantics**IF EXISTS**

Specify IF EXISTS to drop an existing analytic view.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema in which the analytic view exists. If you do not specify a schema, then the database looks for the analytic view in your own schema.

analytic_view_name

Specify the name of the analytic view to drop.

Example

The following statement drops the specified analytic view object:

```
DROP ANALYTIC VIEW sales_av;
```

DROP APPLICATION IDENTITY

Purpose

Use DROP APPLICATION IDENTITY to drop an application identity.

Prerequisites

You must have the DROP APPLICATION IDENTITY system privilege to execute this command.

Syntax**Semantics**

- IF EXISTS:** If you specify IF EXISTS the application identity is dropped if it exists. If the application identity does not exist, no error is thrown.
 If you do not specify IF EXISTS, and the application identity exists, then it will be dropped. If the application identity does not exist, an error is thrown.
- app_identity* :** the name of the application identity to be dropped.

DROP ASSERTION

Purpose

Prerequisites

You must have the `DROP ANY ASSERTION [ ON SCHEMA ...]` privilege to drop assertions in the specified schema or any other schema not your own.

Syntax

Semantics

IF EXISTS

Specify `IF EXISTS` to prevent an error message in case the assertion you are trying to drop does not exist.

You cannot use `IF NOT EXISTS` with `DROP` statements.

Examples

Example 1: Dropping an assertion

The following statement removes the assertion `company_must_have_a_president`:

```
DROP ASSERTION IF EXISTS company_must_have_a_president;
```

If there is no assertion with this name, the statement takes no action and completes without error.

Example 1: Dropping an assertion in another schema

The following statement drops the assertion `salary_within_job_limit` in the HR schema:

```
DROP ASSERTION hr.salary_within_job_limit;
```

If you're not connected as the HR user, your user must have either of these privileges:

```
DROP ANY ASSERTION or DROP ANY ASSERTION ON SCHEMA hr.
```

DROP ATTRIBUTE DIMENSION

Purpose

Use the `DROP ATTRIBUTE DIMENSION` statement to drop an attribute dimension. An `ATTRIBUTE DIMENSION` object is a component of analytic views.

Prerequisites

To drop an attribute dimension in your own schema, you must have the DROP ATTRIBUTE DIMENSION system privilege. To drop an analytic view in another user's schema, you must have the DROP ANY ATTRIBUTE DIMENSION system privilege.

Syntax

drop_attribute_dimension::=

Semantics

IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema in which the attribute dimension exists. If you do not specify a schema, then Oracle Database looks for the attribute dimension in your own schema.

attr_dimension_name

Specify the name of the attribute dimension to drop.

Example

The following statement drops the specified attribute dimension object:

```
DROP ATTRIBUTE DIMENSION product_attr_dim;
```

DROP AUDIT POLICY (Unified Auditing)

This section describes the DROP AUDIT POLICY statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

Purpose

Use the DROP AUDIT POLICY statement to remove a unified audit policy from the database.

① See Also

- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [AUDIT \(Unified Auditing\)](#)
- [NOAUDIT \(Unified Auditing\)](#)

Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

To drop a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To drop a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container.

Syntax

drop_audit_policy::=

Semantics

policy

Specify the name of the unified audit policy you want to drop. The policy must have been created using the CREATE AUDIT POLICY statement.

You can find the names of all unified audit policies by querying the AUDIT_UNIFIED_POLICIES view and the names of all *enabled* unified audit policies by querying the AUDIT_UNIFIED_ENABLED_POLICIES view

Restriction on Dropping Unified Audit Policies

You cannot drop an enabled unified audit policy. You must first disable the policy using the NOAUDIT statement.

① See Also

- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- *Oracle Database Reference* for more information on the AUDIT_UNIFIED_POLICIES and AUDIT_UNIFIED_ENABLED_POLICIES views

Examples

Dropping a Unified Audit Policy: Example

The following statement drops unified audit policy `table_pol`:

```
DROP AUDIT POLICY table_pol;
```

DROP CLUSTER

Purpose

Use the DROP CLUSTER clause to remove a cluster from the database.

Note

When you drop a cluster, any tables in the recycle bin that were once part of that cluster are purged from the recycle bin and can no longer be recovered with a FLASHBACK TABLE operation.

You cannot uncluster an individual table. Instead you must perform these steps:

1. Create a new table with the same structure and contents as the old one, but with no CLUSTER clause.
2. Drop the old table.
3. Use the RENAME statement to give the new table the name of the old one.
4. Grant privileges on the new unclustered table. Grants on the old clustered table do not apply.

See Also

[CREATE TABLE](#), [DROP TABLE](#), [RENAME](#), [GRANT](#) for information on these steps

Prerequisites

The cluster must be in your own schema or you must have the DROP ANY CLUSTER system privilege.

Syntax

drop_cluster ::=

Semantics

IF EXISTS

Specify **IF EXISTS** to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the cluster. If you omit *schema*, then the database assumes the cluster is in your own schema.

cluster

Specify the name of the cluster to be dropped. Dropping a cluster also drops the cluster index and returns all cluster space, including data blocks for the index, to the appropriate tablespace(s).

INCLUDING TABLES

Specify INCLUDING TABLES to drop all tables that belong to the cluster.

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints from tables outside the cluster that refer to primary and unique keys in tables of the cluster. If you omit this clause and such referential integrity constraints exist, then the database returns an error and does not drop the cluster.

Examples**Dropping a Cluster: Examples**

The following examples drop the clusters created in the "[Examples](#)" section of CREATE CLUSTER.

The following statements drops the language cluster:

```
DROP CLUSTER language;
```

The following statement drops the personnel cluster as well as tables dept_10 and dept_20 and any referential integrity constraints that refer to primary or unique keys in those tables:

```
DROP CLUSTER personnel  
  INCLUDING TABLES  
  CASCADE CONSTRAINTS;
```

16

SQL Statements: DROP CONTEXT to DROP JAVA

This chapter contains the following SQL statements:

- [DROP CONTEXT](#)
- [DROP DATABASE](#)
- [DROP DATABASE LINK](#)
- [DROP DIMENSION](#)
- [DROP DIRECTORY](#)
- [DROP DISKGROUP](#)
- [DROP EDITION](#)
- [DROP FLASHBACK ARCHIVE](#)
- [DROP FUNCTION](#)
- [DROP HIERARCHY](#)
- [DROP INDEX](#)
- [DROP INDEXTYPE](#)
- [DROP INMEMORY JOIN GROUP](#)
- [DROP JAVA](#)

DROP CONTEXT

Purpose

Use the DROP CONTEXT statement to remove a context namespace from the database.

Removing a context namespace does not invalidate any context under that namespace that has been set for a user session. However, the context will be invalid when the user next attempts to set that context.

① See Also

[CREATE CONTEXT](#) and *Oracle Database Security Guide* for more information on contexts

Prerequisites

You must have the DROP ANY CONTEXT system privilege.

Syntax

drop_context::=

Semantics

namespace

Specify the name of the context namespace to drop. You cannot drop the built-in namespace USERENV.

See Also

[SYS_CONTEXT](#) for information on the USERENV namespace

Examples

Dropping an Application Context: Example

The following statement drops the context created in [CREATE CONTEXT](#):

```
DROP CONTEXT hr_context;
```

DROP DATA GRANT

Purpose

Use DROP DATA GRANT to drop a data grant and remove the access defined by it to end users and data roles.

Dropping the data grant removes all the data privileges granted in the named grant along with the predicates. Once the data grant is dropped, access provided by the grant is removed.

Prerequisites

You must have the DROP ANY DATA GRANT privilege at the system level or for the specific schema to drop a data grant in a schema not your own. You can drop a data grant in your own schema without any specific privilege.

Syntax

Semantics

- **IF EXISTS:** If you specify IF EXISTS, the data grant is dropped, if it exists. If the data grant does not exist, no error is raised.

If you do not specify `IF EXISTS`, the data grant is dropped, if it exists. If the data grant does not exist, an error is raised.

- *schema*: specifies the owner of the data grant. If omitted, the current schema is used. The schema must be a valid database user.

If the specified schema is not valid, then the statement raises an error.

- *grant_name*: specifies the name of the data grant to be dropped.

Example

```
CREATE OR REPLACE DATA GRANT
  app_admin.ManagerDirectReports AS
  SELECT (ALL COLUMNS EXCEPT ssn)
  ON hr.employees
  WHERE manager = ORA_APP_USER.username
  TO app_manager_role;
```

```
DROP DATA GRANT IF EXISTS app_admin.ManagerDirectReports;
```

DROP DATA ROLE

Purpose

Use `DROP DATA ROLE` to drop a data role.

Prerequisites

You must have the `DROP DATA ROLE` system privilege to execute this command.

Syntax

Semantics

- `IF EXISTS`: If you specify `IF EXISTS` the data role is dropped if it exists. If the data role does not exist, no error is thrown.

If you do not specify `IF EXISTS`, and the data role exists, then it will be dropped. If the data role does not exist, an error is thrown.

- *data_role* : the name of the data role to be dropped.

Example

The following SQL statement drops the existing data role, `manager_role`:

```
DROP DATA ROLE manager_role;
```

DROP DATABASE

Purpose

Note

You cannot roll back a DROP DATABASE statement.

Use the DROP DATABASE statement to drop the database. This statement is useful when you want to drop a test database or drop an old database after successful migration to a new host.

You can issue DROP DATABASE on True Cache to delete all the files that belong to this True Cache. The command only deletes files that belong to this True Cache. You must have started up the True Cache in mount mode.

See Also

Oracle Database Backup and Recovery User's Guide for more information on dropping the database

Prerequisites

You must have the SYSDBA system privilege to issue this statement. The database must be mounted in exclusive and restricted mode, and it must be closed.

Syntax

drop_database::=

→ DROP → DATABASE →

Semantics

When you issue this statement, Oracle Database drops the database and deletes all control files and data files listed in the control file. If the database used a server parameter file (spfile), then the spfile is also deleted.

Archived logs and backups are not removed, but you can use Recovery Manager (RMAN) to remove them. If the database is on raw disks, then this statement does not delete the actual raw disk special files.

Drop True Cache

To drop the True Cache using DROP DATABASE you must mount the database and set restricted mode as follows:

```
STARTUP MOUNT
ALTER SYSTEM ENABLE RESTRICTED SESSION;
DROP DATABASE
```

DROP DATABASE LINK

Purpose

Use the DROP DATABASE LINK statement to remove a database link from the database.

See Also

[CREATE DATABASE LINK](#) for information on creating database links

Prerequisites

A private database link must be in your own schema. To drop a PUBLIC database link, you must have the DROP PUBLIC DATABASE LINK system privilege.

Syntax

drop_database_link::=

Semantics

PUBLIC

You must specify PUBLIC to drop a PUBLIC database link.

dblink

Specify the name of the database link to be dropped.

Restriction on Dropping Database Links

You cannot drop a database link in another user's schema, and you cannot qualify *dblink* with the name of a schema, because periods are permitted in names of database links. Therefore, Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.

IF EXISTS

Specify **IF EXISTS** to drop an existing object.

Specifying **IF NOT EXISTS** with **DROP** results in `ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement`.

Examples

Dropping a Database Link: Example

The following statement drops the public database link named `remote`, which was created in "[Defining a Public Database Link: Example](#)":

```
DROP PUBLIC DATABASE LINK remote;
```

DROP DIMENSION

Purpose

Use the DROP DIMENSION statement to remove the named dimension.

This statement does not invalidate materialized views that use relationships specified in dimensions. However, requests that have been rewritten by query rewrite may be invalidated, and subsequent operations on such views may execute more slowly.

See Also

- [CREATE DIMENSION](#) and [ALTER DIMENSION](#) for information on creating and modifying a dimension
- *Oracle Database Concepts* for general information about dimensions

Prerequisites

The dimension must be in your own schema or you must have the DROP ANY DIMENSION system privilege to use this statement.

Syntax

drop_dimension ::=

Semantics

schema

Specify the name of the schema in which the dimension is located. If you omit *schema*, then Oracle Database assumes the dimension is in your own schema.

dimension

Specify the name of the dimension you want to drop. The dimension must already exist.

Examples

Dropping a Dimension: Example

This example drops the sh.customers_dim dimension:

```
DROP DIMENSION customers_dim;
```

① See Also

"[Creating a Dimension: Examples](#)" and "[Modifying a Dimension: Examples](#)" for examples of creating and modifying this dimension

DROP DIRECTIVE (VALIDATE)

Purpose

Use DROP DIRECTIVE to drop a validation directive. This will cause a cascaded drop of all dependent objects.

Syntax

→ DROP → DIRECTIVE → directive_name →

DROP DIRECTORY

Purpose

Use the DROP DIRECTORY statement to remove a directory object from the database.

① See Also

[CREATE DIRECTORY](#) for information on creating a directory

Prerequisites

To drop a directory, you must have the DROP ANY DIRECTORY system privilege.

① Note

Do not drop a directory when files in the associated file system are being accessed by PL/SQL or OCI programs.

Syntax

drop_directory::=

→ DROP → DIRECTORY → IF → EXISTS → directory_name →

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

directory_name

Specify the name of the directory database object to be dropped.

Oracle Database removes the directory object but does not delete the associated operating system directory on the server file system.

Examples

Dropping a Directory: Example

The following statement drops the directory object bfile_dir:

```
DROP DIRECTORY bfile_dir;
```

📘 See Also

["Creating a Directory: Examples"](#)

DROP DISKGROUP

📘 Note

This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator's Guide*.

Purpose

The DROP DISKGROUP statement lets you drop an Oracle ASM disk group along with all the files in the disk group. Oracle ASM first ensures that no files in the disk group are open. It then drops the disk group and all its member disks and clears the disk header.

📘 See Also

- [CREATE DISKGROUP](#) and [ALTER DISKGROUP](#) for information on creating and modifying disk groups
- *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disks groups to simplify database administration

Prerequisites

You must have the SYSASM system privilege and you must have an Oracle ASM instance started, from which you issue this statement. The disk group to be dropped must be mounted.

Syntax

drop_diskgroup::=

Semantics

diskgroup_name

Specify the name of the disk group you want to drop.

INCLUDING CONTENTS

Specify INCLUDING CONTENTS to confirm that Oracle ASM should drop all the files in the disk group. You must specify this clause if the disk group contains any files.

FORCE

This clause clears the headers on the disk belonging to a disk group that cannot be mounted by the Oracle ASM instance. The disk group cannot be mounted by any instance of the database.

The Oracle ASM instance first determines whether the disk group is being used by any other Oracle ASM instance using the same storage subsystem. If it is being used, and if the disk group is in the same cluster, or on the same node, then the statement fails. If the disk group is in a different cluster, then the system further checks to determine whether the disk group is mounted by any instance in the other cluster. If it is mounted elsewhere, then the statement fails. However, this latter check is not as definitive as the checks for disk groups in the same cluster. Therefore, use this clause with caution.

EXCLUDING CONTENTS

Specify EXCLUDING CONTENTS to ensure that Oracle ASM drops the disk group only when the disk group is empty. This is the default. If the disk group is not empty, then an error will be returned.

Examples

Dropping a Diskgroup: Example

The following statement drops the Oracle ASM disk group dgroup_01, which was created in "[Creating a Diskgroup: Example](#)", and all of the files in the disk group:

```
DROP DISKGROUP dgroup_01 INCLUDING CONTENTS;
```

DROP DOMAIN

Purpose

Use this statement to drop a domain, thereby disassociating the domain from all its dependent objects.

Prerequisites

The domain must be in your own schema or you must have the `DROP ANY DOMAIN` system privilege.

Syntax

drop_domain ::=

Semantics

USECASE

This keyword is optional and is provided for semantic clarity. It indicates that the domain is to describe a data use case.

IF EXISTS

Specify `IF EXISTS` to drop a domain that exists.

You cannot specify `IF NOT EXISTS` with `DROP DOMAIN`. This results in the following error:
ORA-11544:Incorrect IF EXISTS clause for ALTER/DROP statement.

You can drop a domain by specifying its domain name and disassociate it from all its dependent columns. In the following example email is the name of a domain name:

```
DROP DOMAIN email;
```

If a domain is associated with columns, `DROP DOMAIN domain_name` fails with ORA-11502:The domain <domain_name> to be dropped has dependent objects.This includes any tables in the recyclebin.

You can additionally drop a domain by specifying two optional keywords: either `FORCE` or `FORCE PRESERVE` which have different meanings:

FORCE

`DROP DOMAIN domain_name FORCE` disassociates the domain from all its dependent columns. This includes dropping all constraints on columns that were inherited from the domain. Defaults inherited from the domain are also dropped unless these defaults were set specifically on columns.

If you must drop a domain and have dependent tables in the recyclebin, you must use the `FORCE` option.

FORCE PRESERVE

Use `DROP DOMAIN domain_name FORCE PRESERVE` if you want to preserve domain defaults and domain constraints on columns inherited from the domain. You must first specify `FORCE`, in order to specify the `PRESERVE` option. Use this option if you want to temporarily drop the domain and recreate it later with new data and the former dependent columns. In this case you want to ensure that the table data continues to be consistent with the domain definition with all the constraints and defaults on columns inherited from the domain preserved. If you drop a domain with `FORCE PRESERVE` and later recreate the domain and reassociate the column with it, you can end up with a second constraint. In this case, use `ALTER TABLE DROP CONSTRAINT` to drop the second constraint.

If there are no tables or materialized views with columns of the given domain, then `DROP DOMAIN` will invalidate any SQL dependent statements and remove the domain object from the catalog. In this case you can specify `FORCE` and `FORCE PRESERVE` without affecting the domain or the domain's dependent objects.

If there are tables or materialized views with columns of the given domain, `DROP DOMAIN` without the `FORCE` option will fail without affecting the domain or domain's dependent objects.

If there are tables or materialized views with columns of the given domain, `DROP DOMAIN FORCE` will do the following:

- Remove the default expression from any dependent column, if the column has a default expression that was only set as a domain default. If the default expression was added on the column and set as domain default, then default on the column is preserved.
- Remove the domain annotations from all dependent columns
- Preserve collation on any domain dependent columns
- Invalidate all SQL dependent statements in the cursor cache.
- Materialized views (MVs) that reference domain functions like `DOMAIN_DISPLAY`, `DOMAIN_ORDER`, `DOMAIN_NAME` will be invalidated so they can be fully refreshed. MVs that reference columns of a given domain will not be invalidated .
- Remove the domain successfully.

If there are flexible domains referencing the domain, then `DROP DOMAIN` without the `FORCE` option will raise an error, while `DROP DOMAIN FORCE` will drop all flexible dependent domains in `FORCE` mode also.

Examples

The following example drops the domain `day_of_week`. If there are any columns associated with the domain the statement will raise `ORA-11502` and the domain will still be present:

```
DROP DOMAIN day_of_week;
```

The following statement drops the domain `day_of_week`. If there are any columns associated with it, the columns will inherit any defaults and constraints from the domain:

```
DROP DOMAIN day_of_week FORCE PRESERVE;
```

DROP EDITION

Purpose

Use the DROP EDITION statement to drop an edition, along with all actual editionable objects it contains. An actual editionable object is an editionable object that has been created or modified in an edition.

See Also

[CREATE EDITION](#) for a listing of editionable object types

Prerequisites

You must have the DROP ANY EDITION system privilege, granted either directly or through a role.

Syntax

drop_edition::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing edition.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

Objects that are not editionable, or that are editionable but have not been actualized in the current edition, are not dropped.

You must specify CASCADE if the specified edition contains any actual editionable objects.

Restrictions

This statement is subject to the following conditions and restrictions:

- The specified edition cannot have both a parent edition and a child edition.
- DROP EDITION will fail if you attempt to drop the default edition.
- DROP EDITION will fail if you attempt to drop the root edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. Under these circumstances, even DROP EDITION CASCADE will fail. In this case, you can purge all objects from the recycle bin with the PURGE DBA_RECYCLEBIN statement and then drop the edition. Refer to [PURGE](#) for more information.

DROP EDITION will also fail if you attempt to drop the leaf edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. However, under these circumstances, DROP EDITION CASCADE will succeed.

The only type of editioned object that might be in the recycle bin is a trigger.

- DROP EDITION will fail if you attempt to drop an edition that is the current edition in any session.

① See Also

- *Oracle Database Development Guide*
- *Oracle Database PL/SQL Packages and Types Reference*

Examples

For examples that use this statement, refer to [CREATE EDITION](#).

DROP END USER

Purpose

Use DROP END USER to drop an existing end user. Note that you cannot drop an end user if it has an active session.

When a Deep Sec user or role is dropped, the user and the role is removed from the grantee list of existing data grants. If the user or role being dropped is the only grantee of a data grant, the data grant will be dropped when the user or role is dropped.

Prerequisites

You must have the DROP END USER system privilege to execute this command.

Syntax

Semantics

IF EXISTS: If you specify IF EXISTS, and the end user exists, the end user is dropped. If the end user does not exist, no error is thrown.

If you do not specify IF EXISTS, and the end user does not exist, an error is thrown. If the end user exists, then it is dropped.

Example

The following SQL statement drops the end user marvin:

```
DROP END USER marvin;
```

DROP END USER CONTEXT

Purpose

Use DROP END USER CONTEXT to drop an end-user context.

Prerequisites

You do not need additional privileges for dropping an end-user context in your own schema. To drop an end-user context in other schemas you must have the `DROP ANY END USER CONTEXT` system privilege.

Syntax

Semantics

- **IF EXISTS:** If you specify `IF EXISTS` and the end-user context does not exist, no error is raised. If the end-user context exists, then it will be dropped.
If you do not specify `IF EXISTS`, and the end-user context does not exist, an error is raised. If the end-user context exists, then it will be dropped.
- *schema*: schema name of the end-user context definition.
- *name*: name of the end-user context definition.

Example

The following SQL statement drops the end-user context attribute `hcm`:

```
DROP END USER CONTEXT hr.hcm;
```

DROP FLASHBACK ARCHIVE

Purpose

Use the `DROP FLASHBACK ARCHIVE` clause to remove a flashback archive from the system. This statement removes the flashback archive and all the historical data in it, but does not drop the tablespaces that were used by the flashback archive.

Prerequisites

You must have the `FLASHBACK ARCHIVE ADMINISTER` system privilege to drop a flashback archive.

Syntax

drop_flashback_archive::=

Semantics

flashback_archive

Specify the name of the flashback archive you want to drop.

① See Also

[CREATE FLASHBACK ARCHIVE](#) for information on creating flashback archives and for some simple examples of using flashback archives

DROP FUNCTION

Purpose

Functions are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping functions.

Use the DROP FUNCTION statement to remove a standalone stored function from the database.

① Note

Do not use this statement to remove a function that is part of a package. Instead, either drop the entire package using the DROP PACKAGE statement or redefine the package without the function using the CREATE PACKAGE statement with the OR REPLACE clause.

Prerequisites

The function must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

drop_function ::=

**Semantics****IF EXISTS**

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the function. If you omit *schema*, then Oracle Database assumes the function is in your own schema.

function_name

Specify the name of the function to be dropped.

Oracle Database invalidates any local objects that depend on, or call, the dropped function. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped function.

If any statistics types are associated with the function, then the database disassociates the statistics types with the FORCE option and drops any user-defined statistics collected with the statistics type.

See Also

- *Oracle Database Concepts* for more information on how Oracle Database maintains dependencies among schema objects, including remote objects
- [ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

Examples

Dropping a Function: Example

The following statement drops the function SecondMax in the sample schema oe and invalidates all objects that depend upon SecondMax:

```
DROP FUNCTION oe.SecondMax;
```

See Also

Oracle Database PL/SQL Language Reference for the example that creates the SecondMax function

DROP HIERARCHY

Purpose

Use the DROP HIERARCHY statement to drop a hierarchy. A HIERARCHY object is a component of analytic views.

Prerequisites

To drop a hierarchy in your own schema, you must have the DROP HIERARCHY system privilege. To drop a hierarchy in another user's schema, you must have the DROP ANY HIERARCHY system privilege.

Syntax

drop_hierarchy::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema in which the hierarchy exists. If you do not specify a schema, then Oracle Database looks for the hierarchy in your own schema.

hierarchy_name

Specify the name of the hierarchy to drop.

Example

The following statement drops the specified hierarchy object:

```
DROP HIERARCHY product_hier;
```

DROP ICEBERG TABLE

Purpose

An Oracle-native DDL that drops an Iceberg table in a catalog. The catalog needs to be defined with `dbms_catalog.mount_iceberg`.

Prerequisites

Syntax

Semantics

The PURGE option will delete the current metadata file as well as all manifest-list, manifest, and data files associated with the table.

DROP INDEX

Purpose

Use the DROP INDEX statement to remove an index or domain index from the database.

When you drop a global partitioned index, a range-partitioned index, or a hash-partitioned index, all the index partitions are also dropped. If you drop a composite-partitioned index, then all the index partitions and subpartitions are also dropped.

In addition, when you drop a domain index:

- Oracle Database invokes the appropriate routine.
- If any statistics are associated with the domain index, then Oracle Database disassociates the statistics types with the FORCE clause and removes the user-defined statistics collected with the statistics type.

① See Also

- *Oracle Database Data Cartridge Developer's Guide* for information on the routines
- [CREATE INDEX](#) and [ALTER INDEX](#) for information on creating and modifying an index
- The *domain_index_clause* of [CREATE INDEX](#) for more information on domain indexes
- [ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

Prerequisites

The index must be in your own schema or you must have the DROP ANY INDEX system privilege.

Syntax

drop_index::=

Semantics

IF EXISTS

Specify **IF EXISTS** to drop an existing object.

Specifying **IF NOT EXISTS** with **DROP** results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the index. If you omit *schema*, then Oracle Database assumes the index is in your own schema.

index

Specify the name of the index to be dropped. When the index is dropped, all data blocks allocated to the index are returned to the tablespace that contained the index.

ONLINE

Specify **ONLINE** to indicate that DML operations on the table or partition will be allowed while dropping the index.

FORCE

FORCE applies only to domain indexes. This clause drops the domain index even if the `indextype` routine invocation returns an error or the index is marked **IN PROGRESS**. Without **FORCE**, you cannot drop a domain index if its `indextype` routine invocation returns an error or the index is marked **IN PROGRESS**.

Note

When dropping a domain index with **FORCE** option, the index will be dropped regardless of any errors happening in the `indextype` routine. The errors raised by the `indextype` routine are not reported.

Only use the **FORCE** option when the index or index partitions are marked **IN PROGRESS** or when **DROP INDEX** has already failed.

{ DEFERRED | IMMEDIATE } INVALIDATION

This clause lets you control when the database invalidates dependent cursors while dropping the index. It has the same semantics here as for the **ALTER INDEX** statement, with the following addition: When you drop an index with **DEFERRED INVALIDATION**, Oracle database will immediately invalidate any DML statement or query that references the dropped index in its plan.

See [{ DEFERRED | IMMEDIATE } INVALIDATION](#) in the documentation on **ALTER INDEX** for the full semantics of this clause.

Restrictions on Dropping Indexes

The following restrictions apply to dropping indexes:

- You cannot drop a domain index if the index or any of its index partitions is marked **IN PROGRESS**.
- You cannot specify the **ONLINE** clause when dropping a domain index, a cluster index, or an index on a queue table.

Examples**Dropping an Index: Example**

This statement drops an index named `ord_customer_ix_demo`, which was created in "[Compressing an Index: Example](#)":

```
DROP INDEX ord_customer_ix_demo;
```

DROP INDEXTYPE

Purpose

Use the DROP INDEXTYPE statement to drop an indextype as well as any association with a statistics type.

See Also

[CREATE INDEXTYPE](#) for more information on indextypes

Prerequisites

The indextype must be in your own schema or you must have the DROP ANY INDEXTYPE system privilege.

Syntax

drop_indextype::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the indextype. If you omit *schema*, then Oracle Database assumes the indextype is in your own schema.

indextype

Specify the name of the indextype to be dropped.

If any statistics types have been associated with indextype, then the database disassociates the statistics type from the indextype and drops any statistics that have been collected using the statistics type.

See Also

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics associations

FORCE

Specify FORCE to drop the indextype even if the indextype is currently being referenced by one or more domain indexes. Oracle Database marks those domain indexes INVALID. Without FORCE, you cannot drop an indextype if any domain indexes reference the indextype.

Examples

Dropping an Indextype: Example

The following statement drops the indextype `position_indextype`, created in "[Using Extensible Indexing](#)", and marks INVALID any domain indexes defined on this indextype:

```
DROP INDEXTYPE position_indextype FORCE;
```

DROP INMEMORY JOIN GROUP

Purpose

Use the DROP INMEMORY JOIN GROUP statement to remove a join group from the database.

① See Also

- [CREATE INMEMORY JOIN GROUP](#) and [ALTER INMEMORY JOIN GROUP](#)
- *Oracle Database In-Memory Guide* for more information on join groups

Prerequisites

If the join group is in another user's schema, then you must have the DROP ANY TABLE system privilege.

Syntax

drop_inmemory_join_group::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the join group. If you omit *schema*, then the database assumes the join group is in your own schema.

join_group

Specify the name of the join group to be dropped.

You can view existing join groups by querying the DBA_JOINGROUPS or USER_JOINGROUPS data dictionary view. Refer to *Oracle Database Reference* for more information on these views.

Examples

The following statement drops the join group prod_id1:

```
DROP INMEMORY JOIN GROUP prod_id1;
```

DROP JAVA

Purpose

Use the DROP JAVA statement to drop a Java source, class, or resource schema object.

① See Also

- [CREATE JAVA](#) for information on creating Java objects
- *Oracle Database Java Developer's Guide* for more information on resolving Java sources, classes, and resources

Prerequisites

The Java source, class, or resource must be in your own schema or you must have the DROP ANY PROCEDURE system privilege. You also must have the EXECUTE object privilege on Java classes to use this command.

Syntax

drop_java::=

**Semantics****IF EXISTS**

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

JAVA SOURCE

Specify SOURCE to drop a Java source schema object and all Java class schema objects derived from it.

JAVA CLASS

Specify CLASS to drop a Java class schema object.

JAVA RESOURCE

Specify RESOURCE to drop a Java resource schema object.

object_name

Specify the name of an existing Java class, source, or resource schema object. Enclose the *object_name* in double quotation marks to preserve lower- or mixed-case names.

Examples**Dropping a Java Class Object: Example**

The following statement drops the Java class Agent, created in "[Creating a Java Class Object: Example](#)":

```
DROP JAVA CLASS "Agent";
```

17

SQL Statements: DROP LIBRARY to DROP SYNONYM

This chapter contains the following SQL statements:

- [DROP LIBRARY](#)
- [DROP LOCKDOWN PROFILE](#)
- [DROP MATERIALIZED VIEW](#)
- [DROP MATERIALIZED VIEW LOG](#)
- [DROP MATERIALIZED ZONEMAP](#)
- [DROP OPERATOR](#)
- [DROP OUTLINE](#)
- [DROP PACKAGE](#)
- [DROP PLUGGABLE DATABASE](#)
- [DROP PROCEDURE](#)
- [DROP PROFILE](#)
- [DROP RESTORE POINT](#)
- [DROP ROLE](#)
- [DROP ROLLBACK SEGMENT](#)
- [DROP SEQUENCE](#)
- [DROP SYNONYM](#)

DROP LIBRARY

Purpose

Use the DROP LIBRARY statement to remove an external procedure library from the database.

① See Also

[CREATE LIBRARY](#) for information on creating a library

Prerequisites

You must have the DROP ANY LIBRARY system privilege.

Syntax

drop_library::=

Semantics

IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

library_name

Specify the name of the external procedure library being dropped.

Examples

Dropping a Library: Example

The following statement drops the `ext_lib` library:

```
DROP LIBRARY ext_lib;
```

DROP LOCKDOWN PROFILE

Purpose

Use the `DROP LOCKDOWN PROFILE` statement to remove a PDB lockdown profile from the database. A PDB that was assigned the dropped profile will continue to be assigned the profile, but will not be subject to the restrictions imposed by the dropped profile.

If the `PDB_LOCKDOWN` initialization parameter for a CDB, an application root, or a PDB has the value of the dropped lockdown profile, then the restrictions imposed by the dropped profile will be disabled when you drop it. However, the value of the `PDB_LOCKDOWN` initialization parameter will remain until you explicitly unset it.

See Also

- [CREATE LOCKDOWN PROFILE](#) and [ALTER LOCKDOWN PROFILE](#)
- *Oracle Database Security Guide* for more information on PDB lockdown profiles

Prerequisites

- You must issue this statement from the CDB Root or the Application Root.
- You must have the `DROP LOCKDOWN PROFILE` system privilege in the container where you mean to issue the statement.

Syntax

drop_lockdown_profile::=

Semantics

profile_name

Specify the name of the PDB lockdown profile to be dropped.

You can find the names of existing PDB lockdown profiles by querying the `DBA_LOCKDOWN_PROFILES` data dictionary view.

See Also

Oracle Database Reference for more information on the `DBA_LOCKDOWN_PROFILES` data dictionary view and the `PDB_LOCKDOWN` initialization parameter

Example

The following statement drops PDB lockdown profile `hr_prof`:

```
DROP LOCKDOWN PROFILE hr_prof;
```

DROP MATERIALIZED VIEW

Purpose

Use the `DROP MATERIALIZED VIEW` statement to remove an existing materialized view from the database.

When you drop a materialized view, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the materialized view.

Note

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

See Also

- [CREATE MATERIALIZED VIEW](#) for more information on the various types of materialized views
- [ALTER MATERIALIZED VIEW](#) for information on modifying a materialized view
- *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

Prerequisites

The materialized view must be in your own schema or you must have the DROP ANY MATERIALIZED VIEW system privilege. You must also have the privileges to drop the internal table, views, and index that the database uses to maintain the materialized view data.

See Also

[DROP TABLE](#), [DROP VIEW](#), and [DROP INDEX](#) for information on privileges required to drop objects that the database uses to maintain the materialized view

Syntax

drop_materialized_view::=

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the materialized view. If you omit *schema*, then Oracle Database assumes the materialized view is in your own schema.

materialized_view

Specify the name of the existing materialized view to be dropped.

- If you drop a simple materialized view that is the least recently refreshed materialized view of a master table, then the database automatically purges from the master table materialized view log only the rows needed to refresh the dropped materialized view.

- If you drop a materialized view that was created on a prebuilt table, then the database drops the materialized view, and the prebuilt table reverts to its identity as a table.
- When you drop a master table, the database does not automatically drop materialized views based on the table. However, the database returns an error when it tries to refresh a materialized view based on a master table that has been dropped.
- If you drop a materialized view, then any compiled requests that were rewritten to use the materialized view will be invalidated and recompiled automatically. If the materialized view was prebuilt on a table, then the table is not dropped, but it can no longer be maintained by the materialized view refresh mechanism.

PRESERVE TABLE Clause

This clause lets you retain the materialized view container table and its contents after the materialized view object is dropped. The resulting table has the same name as the dropped materialized view.

Oracle Database removes all metadata associated with the materialized view. However, indexes created on the container table automatically during creation of the materialized view are preserved, with one exception: the index created during the creation of a rowid materialized view is dropped. Also, if the materialized view has any nested table columns, then the storage tables for those columns are preserved, along with their metadata.

Restriction on the PRESERVE TABLE Clause

This clause is not valid for materialized views that have been imported from releases earlier than Oracle9i, when these objects were called "snapshots".

Examples

Dropping a Materialized View: Examples

The following statement drops the materialized view emp_data in the sample schema hr:

```
DROP MATERIALIZED VIEW emp_data;
```

The following statement drops the sales_by_month_by_state materialized view and the underlying table of the materialized view, unless the underlying table was registered in the CREATE MATERIALIZED VIEW statement with the ON PREBUILT TABLE clause:

```
DROP MATERIALIZED VIEW sales_by_month_by_state;
```

DROP MATERIALIZED VIEW LOG

Purpose

Use the DROP MATERIALIZED VIEW LOG statement to remove a materialized view log from the database.

Note

The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

① See Also

- [CREATE MATERIALIZED VIEW](#) and [ALTER MATERIALIZED VIEW](#) for more information on materialized views
- [CREATE MATERIALIZED VIEW LOG](#) for information on materialized view logs
- *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

Prerequisites

To drop a materialized view log, you must have the privileges needed to drop a table.

① See Also

[DROP TABLE](#)

Syntax

drop_materialized_view_log::=

**Semantics****IF EXISTS**

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the materialized view log and its master table. If you omit *schema*, then Oracle Database assumes the materialized view log and master table are in your own schema.

table

Specify the name of the master table associated with the materialized view log to be dropped.

After you drop a materialized view log that was created FOR FAST REFRESH, some materialized views based on the materialized view log master table can no longer be fast refreshed. These materialized views include rowid materialized views, primary key materialized views, and subquery materialized views.

① See Also

Oracle Database Data Warehousing Guide for a description of these types of materialized views

After you drop a materialized view log that was created FOR SYNCHRONOUS REFRESH (a staging log), the materialized views based on the staging log master table can no longer be synchronous refreshed.

Examples**Dropping a Materialized View Log: Example**

The following statement drops the materialized view log on the `oe.customers` master table:

```
DROP MATERIALIZED VIEW LOG ON customers;
```

DROP MATERIALIZED ZONEMAP

Purpose

Use the DROP MATERIALIZED ZONEMAP statement to remove an existing zone map from the database.

Prerequisites

The zone map must be in your own schema or you must have the DROP ANY MATERIALIZED VIEW system privilege. You must also have the privileges to drop the internal table and indexes that the database uses to maintain the zone map data.

① See Also

[DROP TABLE](#) and [DROP INDEX](#) for information on privileges required to drop objects that the database uses to maintain the zone map

Syntax

drop_materialized_zonemap::=

**Semantics****IF EXISTS**

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the zone map. If you omit *schema*, then Oracle Database assumes the zone map is in your own schema.

zonemap_name

Specify the name of the existing zone map to be dropped.

Example**Dropping a Zone Map: Examples**

The following statement drops the zone map `sales_zmap`:

```
DROP MATERIALIZED ZONEMAP sales_zmap;
```

DROP MLE ENV

Purpose

Drop an existing environment with `DROP MLE ENV`.

Prerequisites

You must have the `DROP ANY MLE` privilege to drop an environment in schemas other than your own. No privilege is needed to drop an environment in your own schema.

Syntax**Semantics**

Specify `IF EXISTS` to drop an existing MLE environment.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

See Also

- [CREATE MLE ENV](#)
- [ALTER MLE ENV](#)
- [CREATE MLE MODULE](#)

DROP MLE MODULE

Purpose

You can drop a previously deployed MLE module using `DROP MLE MODULE`.

Syntax**Semantics**

Specify IF EXISTS to drop an existing MLE module.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

module_name refers to the module name.

See Also

- [CREATE MLE MODULE](#)
- [ALTER MLE MODULE](#)

DROP OPERATOR

Purpose

Use the DROP OPERATOR statement to drop a user-defined operator.

See Also

- [CREATE OPERATOR](#) and [ALTER OPERATOR](#) for information on creating and modifying operators
- ["User-Defined Operators"](#) and *Oracle Database Data Cartridge Developer's Guide* for more information on operators in general
- [ALTER INDEXTYPE](#) for information on dropping an operator of a user-defined indextype

Prerequisites

The operator must be in your schema or you must have the DROP ANY OPERATOR system privilege.

Syntax

drop_operator::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the operator. If you omit *schema*, then Oracle Database assumes the operator is in your own schema.

operator

Specify the name of the operator to be dropped.

FORCE

Specify FORCE to drop the operator even if it is currently being referenced by one or more schema objects, such as indextypes, packages, functions, procedures, and so on. The database marks any such dependent objects INVALID. Without FORCE, you cannot drop an operator if any schema objects reference it.

Examples

Dropping a User-Defined Operator: Example

The following statement drops the operator eq_op:

```
DROP OPERATOR eq_op;
```

Because the FORCE clause is not specified, this operation will fail if any of the bindings of this operator are referenced by an indextype.

DROP OUTLINE

Purpose

Note

- Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.
- You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.
- **See Also:** *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `DROP OUTLINE` statement to drop a stored outline.

See Also

[CREATE OUTLINE](#) for information on creating an outline

Prerequisites

To drop an outline, you must have the `DROP ANY OUTLINE` system privilege.

Syntax

drop_outline::=

Semantics

outline

Specify the name of the outline to be dropped.

After the outline is dropped, if the SQL statement for which the stored outline was created is compiled, then the optimizer generates a new execution plan without the influence of the outline.

Examples

Dropping an Outline: Example

The following statement drops the stored outline called salaries.

```
DROP OUTLINE salaries;
```

DROP PACKAGE

Purpose

Packages are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping packages.

Use the DROP PACKAGE statement to remove a stored package from the database. This statement drops the body and specification of a package.

Note

Do not use this statement to remove a single object from a package. Instead, re-create the package without the object using the CREATE PACKAGE and CREATE PACKAGE BODY statements with the OR REPLACE clause.

Prerequisites

The package must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

drop_package ::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

BODY

Specify BODY to drop only the body of the package. If you omit this clause, then Oracle Database drops both the body and specification of the package.

When you drop only the body of a package but not its specification, the database does not invalidate dependent objects. However, you cannot call one of the procedures or stored functions declared in the package specification until you re-create the package body.

schema

Specify the schema containing the package. If you omit *schema*, then the database assumes the package is in your own schema.

package

Specify the name of the package to be dropped.

Oracle Database invalidates any local objects that depend on the package specification. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped package.

If any statistics types are associated with the package, then the database disassociates the statistics types with the FORCE clause and drops any user-defined statistics collected with the statistics types.

 See Also

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#)

Examples**Dropping a Package: Example**

The following statement drops the specification and body of the emp_mgmt package, invalidating all objects that depend on the specification. See *Oracle Database PL/SQL Language Reference* for the example that creates this package.

```
DROP PACKAGE emp_mgmt;
```

DROP PLUGGABLE DATABASE

Purpose

Use the DROP PLUGGABLE DATABASE statement to drop a pluggable database (PDB). The PDB can be a traditional PDB, an application container, an application seed, or an application PDB.

When you drop a PDB, the control file of the multitenant container database (CDB) is modified to remove all references to the dropped PDB and its data files. Archived logs and backups associated with the dropped PDB are not deleted. You can delete them using Oracle Recovery Manager (RMAN), or you can retain them in case you subsequently want to perform point-in-time recovery of the PDB.

 Caution

You cannot roll back a DROP PLUGGABLE DATABASE statement.

Prerequisites

You must be connected to a CDB.

To drop a traditional PDB or an application container, the current container must be the root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root and locally in traditional PDB or application container you want to drop. The application container must be empty, that is, it must not contain an application seed or any application PDBs.

To drop an application seed, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root.

To drop an application PDB, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root, and locally in the application PDB you want to drop.

To specify KEEP DATAFILES (the default), the PDB you want to drop must be unplugged.

To specify INCLUDING DATAFILES, the PDB you want to drop must be in mounted mode or it must be unplugged.

Syntax

drop_pluggable_database::=

Semantics

pdb_name

Specify the name of the PDB you want to drop. You cannot drop the seed (PDB\$SEED). However, you can drop an application seed.

FORCE

Use FORCE to drop an orphaned application root container.

FORCE requires the following condition: the APP_ROOT_CLONE must be closed, and the APP_CDB must be open.

To close the APP_ROOT_CLONE, you must set the variable `_ORACLE_SCRIPT` to true using ALTER SESSION.

Keeping APP_CDB open follow the instructions to close the APP_ROOT_CLONE:

```

ALTER SESSION SET _ORACLE_SCRIPT=true ;
ALTER PLUGGABLE DATABASE APP_ROOT_CLONE CLOSE;
DROP PLUGGABLE DATABASE APP_ROOT_CLONE FORCE INCLUDING DATAFILES;
  
```

See Also

Removing a PDB

KEEP DATAFILES

Specify **KEEP DATAFILES** to retain the data files associated with the PDB after the PDB is dropped. The temp file for the PDB is deleted because it is no longer needed. This is the default.

Keeping data files may be useful in scenarios where a PDB that is unplugged from one CDB is plugged into another CDB, with both CDBs sharing storage devices.

INCLUDING DATAFILES

Specify **INCLUDING DATAFILES** to delete the data files associated with the PDB being dropped. The temp file for the PDB is also deleted.

Restriction on Dropping SNAPSHOT COPY PDBs

If a PDB was created with the **SNAPSHOT COPY** clause, then you must specify **INCLUDING DATAFILES** when you drop the PDB.

Examples

Dropping a PDB: Example

The following statement drops the PDB `pdb1` and its associated data files:

```
DROP PLUGGABLE DATABASE pdb1
INCLUDING DATAFILES;
```

DROP PMEM FILESTORE

Purpose

You can drop a PMEM file store with this command.

Syntax

drop_pmem_filestore::=

Semantics

INCLUDING CONTENTS

Specify **INCLUDING CONTENTS** to confirm that Oracle should remove all the files in the PMEM file store.

EXCLUDING CONTENTS

Specify **EXCLUDING CONTENTS** to ensure that Oracle drops the PMEM file store only when the file store is empty.

FORCE

Specify **FORCE** along with **INCLUDING CONTENTS** if you suspect that the file store is corrupt.

Note that this option does not check if the file store has content in it prior to deleting it.

If you specify neither **INCLUDING CONTENTS** nor **EXCLUDING CONTENTS**, you must ensure that the file store is empty. **EXCLUDING CONTENTS** is the default behavior.

Example

```
DROP PMEM FILESTORE ccloud_db_1 EXCLUDING CONTENTS
```

DROP PROCEDURE

Purpose

Procedures are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping procedures.

Use the **DROP PROCEDURE** statement to remove a standalone stored procedure from the database. Do not use this statement to remove a procedure that is part of a package. Instead, either drop the entire package using the **DROP PACKAGE** statement, or redefine the package without the procedure using the **CREATE PACKAGE** statement with the **OR REPLACE** clause.

Prerequisites

The procedure must be in your own schema or you must have the **DROP ANY PROCEDURE** system privilege.

Syntax

drop_procedure::=

**Semantics****IF EXISTS**

Specify **IF EXISTS** to drop an existing object.

Specifying **IF NOT EXISTS** with **DROP** results in ORA-11544: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

schema

Specify the schema containing the procedure. If you omit *schema*, then Oracle Database assumes the procedure is in your own schema.

procedure

Specify the name of the procedure to be dropped.

When you drop a procedure, Oracle Database invalidates any local objects that depend upon the dropped procedure. If you subsequently reference one of these objects, then the database

tries to recompile the object and returns an error message if you have not re-created the dropped procedure.

Examples

Dropping a Procedure: Example

The following statement drops the procedure `remove_emp` owned by the user `hr` and invalidates all objects that depend upon `remove_emp`:

```
DROP PROCEDURE hr.remove_emp;
```

DROP PROFILE

Purpose

Use the `DROP PROFILE` statement to remove a profile from the database. You can drop any profile except the `DEFAULT` profile.

See Also

[CREATE PROFILE](#) and [ALTER PROFILE](#) on creating and modifying a profile

Prerequisites

You must have the `DROP PROFILE` system privilege.

Syntax

drop_profile ::=

Semantics

profile

Specify the name of the profile to be dropped.

CASCADE

Specify `CASCADE` to deassign the profile from any users to whom it is assigned. Oracle Database automatically assigns the `DEFAULT` profile to such users. You must specify this clause to drop a profile that is currently assigned to users.

Examples

Dropping a Profile: Example

The following statement drops the profile `app_user`, which was created in "[Creating a Profile: Example](#)". Oracle Database drops the profile `app_user` and assigns the `DEFAULT` profile to any users currently assigned the `app_user` profile:

```
DROP PROFILE app_user CASCADE;
```

DROP PROPERTY GRAPH

Purpose

You can drop property graphs with `DROP PROPERTY GRAPH`.

Prerequisites

Like tables and views, you can drop a property graph in your own schema. To drop a property graph in any schema except SYS and AUDSYS, you must have the `DROP ANY PROPERTY GRAPH` privilege.

Syntax

drop_property_graph::=

Semantics

IF EXISTS

Specify `IF EXISTS` to drop an existing property graph.

If you specify `IF NOT EXISTS` with `DROP`, the command fails with the error message: Incorrect `IF EXISTS` clause for ALTER/DROP statement.

DROP RESTORE POINT

Purpose

Use the `DROP RESTORE POINT` statement to remove a normal restore point or a guaranteed restore point from the database.

- You need not drop normal restore points. The database automatically drops the oldest restore points when necessary, as described in the semantics for [restore point](#). However, you can drop a normal restore point if you want to reuse the name.
- Guaranteed restore points are not dropped automatically. Therefore, if you want to remove a guaranteed restore point from the database, then you must do so explicitly using this statement.

See Also

[CREATE RESTORE POINT](#), [FLASHBACK DATABASE](#), and [FLASHBACK TABLE](#) for information on creating and using restore points

Prerequisites

To drop a normal restore point, you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSBACKUP`, or `SYSDG` system privilege.

To drop a guaranteed restore point, you must fulfill *one* of the following conditions:

- You must connect `AS SYSDBA`, or `AS SYSBACKUP`, or `AS SYSDG`.
- You must have been granted the `SYSDBA` privilege, and be using a multitenant database.
- You must be running as user `SYS`, and be using a multitenant database.

You can drop a restore point when connected to a multitenant container database (CDB) as follows:

- To drop a normal CDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To drop a guaranteed CDB restore point, the current container must be the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To drop a normal PDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.
- To drop a guaranteed PDB restore point, the current container must be the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.

Syntax

drop_restore_point::=

Semantics

restore_point

Specify the name of the restore point you want to drop.

FOR PLUGGABLE DATABASE

This clause enables you to drop a PDB restore point when you are connected to the root. For *pdb_name*, specify the name of the PDB that contains the restore point you want to drop.

If you are connected to the PDB from which you want to drop the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

Examples

Dropping a Restore Point: Example

The following example drops the good_data restore point, which was created in "[Creating and Using a Restore Point: Example](#)":

```
DROP RESTORE POINT good_data;
```

DROP ROLE

Purpose

Use the DROP ROLE statement to remove a role from the database. When you drop a role, the database revokes it from all users and roles to whom it has been granted and removes it from the database. User sessions in which the role is already enabled are not affected. However, no new user session can enable the role after it is dropped.

① See Also

- [CREATE ROLE](#) and [ALTER ROLE](#) for information on creating roles and changing the authorization needed to enable a role
- [SET ROLE](#) for information on disabling roles for the current session

Prerequisites

You must have been granted the role with the ADMIN OPTION or you must have the DROP ANY ROLE system privilege.

Syntax

drop_role::=

Semantics

role

Specify the name of the role to be dropped.

Examples

Dropping a Role: Example

To drop the role dw_manager, which was created in "[Creating a Role: Example](#)", issue the following statement:

```
DROP ROLE dw_manager;
```

DROP ROLLBACK SEGMENT

Purpose

Use the DROP ROLLBACK SEGMENT to remove a rollback segment from the database. When you drop a rollback segment, all space allocated to the rollback segment returns to the tablespace.

Note

If your database is running in automatic undo mode, then this is the only valid operation on rollback segments. In that mode, you cannot create or alter a rollback segment.

Prerequisites

You must have the DROP ROLLBACK SEGMENT system privilege, and the rollback segment must be offline.

Syntax

drop_rollback_segment::=

Semantics

rollback_segment

Specify the name the rollback segment to be dropped.

Restrictions on Dropping Rollback Segments

This statement is subject to the following restrictions:

- You can drop a rollback segment only if it is offline. To determine whether a rollback segment is offline, query the data dictionary view DBA_ROLLBACK_SEGS. Offline rollback segments have the value AVAILABLE in the STATUS column. You can take a rollback segment offline with the OFFLINE clause of the ALTER ROLLBACK SEGMENT statement.
- You cannot drop the SYSTEM rollback segment.

Examples

Dropping a Rollback Segment: Example

The following syntax drops the rollback segment created in "[Creating a Rollback Segment: Example](#)":

```
DROP ROLLBACK SEGMENT rbs_one;
```

DROP SEQUENCE

Purpose

Use the DROP SEQUENCE statement to remove a sequence from the database.

You can also use this statement to restart a sequence by dropping and then re-creating it. For example, if you have a sequence with a current value of 150 and you would like to restart the sequence with a value of 27, then you can drop the sequence and then re-create it with the same name and a START WITH value of 27.

① See Also

[CREATE SEQUENCE](#) and [ALTER SEQUENCE](#) for more information on creating and modifying a sequence

Prerequisites

The sequence must be in your own schema or you must have the DROP ANY SEQUENCE system privilege.

Syntax

drop_sequence ::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the sequence. If you omit *schema*, then Oracle Database assumes the sequence is in your own schema.

sequence_name

Specify the name of the sequence to be dropped.

Examples

Dropping a Sequence: Example

The following statement drops the sequence customers_seq owned by the user oe, which was created in "[Creating a Sequence: Example](#)". To issue this statement, you must either be connected as user oe or have the DROP ANY SEQUENCE system privilege:

```
DROP SEQUENCE oe.customers_seq;
```

DROP SYNONYM

Purpose

Use the DROP SYNONYM statement to remove a synonym from the database or to change the definition of a synonym by dropping and re-creating it.

① See Also

[CREATE SYNONYM](#) for more information on synonyms

Prerequisites

To drop a private synonym, either the synonym must be in your own schema or you must have the DROP ANY SYNONYM system privilege.

To drop a PUBLIC synonym, you must have the DROP PUBLIC SYNONYM system privilege.

Syntax

drop_synonym::=

drop_synonym::=

Semantics

PUBLIC

You must specify **PUBLIC** to drop a public synonym. You cannot specify *schema* if you have specified **PUBLIC**.

IF EXISTS

Specify **IF EXISTS** to drop an existing object.

Specifying **IF NOT EXISTS** with **DROP** results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the synonym. If you omit *schema*, then Oracle Database assumes the synonym is in your own schema.

synonym

Specify the name of the synonym to be dropped.

If you drop a synonym for the master table of a materialized view, and if the defining query of the materialized view specified the synonym rather than the actual table name, then Oracle Database marks the materialized view unusable.

If an object type synonym has any dependent tables or user-defined types, then you cannot drop the synonym unless you also specify **FORCE**.

FORCE

Specify **FORCE** to drop the synonym even if it has dependent tables or user-defined types.

Note

Oracle does not recommend that you specify **FORCE** to drop object type synonyms with dependencies. This operation can result in invalidation of other user-defined types or marking **UNUSED** the table columns that depend on the synonym. For information about type dependencies, see *Oracle Database Object-Relational Developer's Guide*.

Examples

Dropping a Synonym: Example

To drop the public synonym named `customers`, which was created in "[Oracle Database Resolution of Synonyms: Example](#)", issue the following statement:

```
DROP PUBLIC SYNONYM customers;
```

18

SQL Statements: DROP TABLE to LOCK TABLE

This chapter contains the following SQL statements:

- [DROP TABLE](#)
- [DROP TABLESPACE](#)
- [DROP TABLESPACE SET](#)
- [DROP TRIGGER](#)
- [DROP TYPE](#)
- [DROP TYPE BODY](#)
- [DROP USER](#)
- [DROP VIEW](#)
- [EXPLAIN PLAN](#)
- [FLASHBACK DATABASE](#)
- [FLASHBACK TABLE](#)
- [GRANT](#)
- [INSERT](#)
- [LOCK TABLE](#)

DROP TABLE

Purpose

Use the DROP TABLE statement to move a table or object table to the recycle bin or to remove the table and all its data from the database entirely.

Note

Unless you specify the PURGE clause, the DROP TABLE statement does not result in space being released back to the tablespace for use by other objects, and the space continues to count toward the user's space quota.

For an external table, this statement removes only the table metadata in the database. It has no effect on the actual data, which resides outside of the database.

When you drop a table that is part of a cluster, the table is moved to the recycle bin. However, if you subsequently drop the cluster, then the table is purged from the recycle bin and can no longer be recovered with a FLASHBACK TABLE operation.

Dropping a table invalidates dependent objects and removes object privileges on the table. If you want to re-create the table, then you must regrant object privileges on the table, re-create the indexes, integrity constraints, and triggers for the table, and respecify its storage parameters. Truncating has none of these effects. Therefore, removing rows with the TRUNCATE statement can be more efficient than dropping and re-creating a table.

When you drop a table, data grants on the object are also dropped.

① See Also

- [CREATE TABLE](#) and [ALTER TABLE](#) for information on creating and modifying tables
- [TRUNCATE TABLE](#) and [DELETE](#) for information on removing data from a table
- [FLASHBACK TABLE](#) for information on retrieving a dropped table from the recycle bin

Prerequisites

The table must be in your own schema or you must have the DROP ANY TABLE system privilege.

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

Dropping Private Temporary Tables

You can drop a private temporary table using the existing DROP TABLE command. Dropping a private temporary table will not commit an existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a dropped private temporary table will not go into the RECYCLEBIN.

Dropping Blockchain and Immutable Tables

Use the DROP TABLE statement to drop a blockchain or immutable table. It is recommended that you include the PURGE option while dropping these tables. Dropping a blockchain or immutable table removes its definition from the data dictionary, deletes all its rows, and deletes any indexes and triggers defined on the table.

The blockchain or immutable table must be contained in your schema, or you must have the DROP ANY TABLE system privilege.

A blockchain or immutable table can be dropped only after it has not been modified for a period of time that is defined by its retention period.

An empty blockchain or immutable table can be dropped regardless of its retention period.

Syntax

drop_table::=

Semantics

IF EXISTS

Specifying `IF EXISTS` drops the table if it exists.

Using `IF NOT EXISTS` with `DROP TABLE` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

schema

Specify the schema containing the table. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

table

Specify the name of the table to be dropped. Oracle Database automatically performs the following operations:

- All rows from the table are dropped.
- All table indexes and domain indexes are dropped, as well as any triggers defined on the table, regardless of who created them or whose schema contains them. If *table* is partitioned, then any corresponding local index partitions are also dropped.
- All the storage tables of nested tables and LOBs of *table* are dropped.
- When you drop a range-, hash-, or list-partitioned table, then the database drops all the table partitions. If you drop a composite-partitioned table, then all the partitions and subpartitions are also dropped.
- When you drop a partitioned table with the `PURGE` keyword, the statement executes as a series of subtransactions, each of which drops a subset of partitions or subpartitions and their metadata. This division of the drop operation into subtransactions optimizes the processing of internal system resource consumption (for example, the library cache), especially for the dropping of very large partitioned tables. As soon as the first subtransaction commits, the table is marked `UNUSABLE`. If any of the subtransactions fails, then the only operation allowed on the table is another `DROP TABLE ... PURGE` statement. Such a statement will resume work from where the previous `DROP TABLE` statement failed, assuming that you have corrected any errors that the previous operation encountered.

You can list the tables marked `UNUSABLE` by such a drop operation by querying the `status` column of the `*_TABLES`, `*_PART_TABLES`, `*_ALL_TABLES`, or `*_OBJECT_TABLES` data dictionary views, as appropriate.

See Also

Oracle Database VLDB and Partitioning Guide for more information on dropping partitioned tables.

- For an index-organized table, any mapping tables defined on the index-organized table are dropped.
- For a domain index, the appropriate drop routines are invoked. Refer to *Oracle Database Data Cartridge Developer's Guide* for more information on these routines.

- If any statistics types are associated with the table, then the database disassociates the statistics types with the FORCE clause and removes any user-defined statistics collected with the statistics type.

See Also

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

- If the table is not part of a cluster, then the database returns all data blocks allocated to the table and its indexes to the tablespaces containing the table and its indexes.

To drop a cluster and all its the tables, use the DROP CLUSTER statement with the INCLUDING TABLES clause to avoid dropping each table individually. See [DROP CLUSTER](#).

- If the table is a base table for a view, a container or master table of a materialized view, or if it is referenced in a stored procedure, function, or package, then the database invalidates these dependent objects but does not drop them. You cannot use these objects unless you re-create the table or drop and re-create the objects so that they no longer depend on the table.

If you choose to re-create the table, then it must contain all the columns selected by the subqueries originally used to define the materialized views and all the columns referenced in the stored procedures, functions, or packages. Any users previously granted object privileges on the views, stored procedures, functions, or packages need not be regranted these privileges.

If the table is a master table for a materialized view, then the materialized view can still be queried, but it cannot be refreshed unless the table is re-created so that it contains all the columns selected by the defining query of the materialized view.

If the table has a materialized view log, then the database drops this log and any other direct-path INSERT refresh information associated with the table.

Restrictions on Dropping Tables

- You cannot directly drop the storage table of a nested table. Instead, you must drop the nested table column using the ALTER TABLE ... DROP COLUMN clause.
- You cannot drop the parent table of a reference-partitioned table. You must first drop all reference-partitioned child tables.
- You cannot drop a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback archive.

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the dropped table, and all SQL assertions that reference the dropped table.

As with foreign keys the table will not be dropped if there is a SQL assertion referencing it and this clause is omitted.

If you omit this clause, and such referential integrity constraints exist, then the database returns an error and does not drop the table.

PURGE

Specify PURGE if you want to drop the table and release the space associated with it in a single step. If you specify PURGE, then the database does not place the table and its dependent objects into the recycle bin.

Note

You cannot roll back a DROP TABLE statement with the PURGE clause, nor can you recover the table if you have dropped it with the PURGE clause.

Using this clause is equivalent to first dropping the table and then purging it from the recycle bin. This clause lets you save one step in the process. It also provides enhanced security if you want to prevent sensitive material from appearing in the recycle bin.

See Also

Oracle Database Administrator's Guide for information on the recycle bin and naming conventions for objects in the recycle bin

Examples

Dropping a Table: Example

The following statement drops the oe.list_customers table created in "[List Partitioning Example](#)".

```
DROP TABLE list_customers PURGE;
```

DROP TABLESPACE

Purpose

Use the DROP TABLESPACE statement to remove a tablespace from the database.

When you drop a tablespace, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace.

See Also

[CREATE TABLESPACE](#) and [ALTER TABLESPACE](#) for information on creating and modifying a tablespace

Prerequisites

You must have the DROP TABLESPACE system privilege. You cannot drop a tablespace if it contains any rollback segments holding active transactions.

Syntax

drop_tablespace::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing tablespace.

Specifying IF NOT EXISTS with ALTER results in error: Incorrect IF EXISTS clause for ALTER/DROP statement.

tablespace

Specify the name of the tablespace to be dropped, including those of shadow tablespaces, that store lost write protection updates.

You can drop a tablespace regardless of whether it is online or offline. Oracle recommends that you take the tablespace offline before dropping it to ensure that no SQL statements in currently running transactions access any of the objects in the tablespace.

You cannot drop the SYSTEM tablespace. You can drop the SYSAUX tablespace only if you have the SYSDBA system privilege and you have started the database in UPGRADE mode.

You may want to alert any users who have been assigned the tablespace as either a default or temporary tablespace. After the tablespace has been dropped, these users cannot allocate space for objects or sort areas in the tablespace. You can reassign users new default and temporary tablespaces with the ALTER USER statement.

Any objects that were previously dropped from the tablespace and moved to the recycle bin are purged from the recycle bin. Oracle Database removes from the data dictionary all metadata about the tablespace and all data files and temp files in the tablespace. The database also automatically drops from the operating system any Oracle-managed data files and temp files in the tablespace. Other data files and temp files are not removed from the operating system unless you specify INCLUDING CONTENTS AND DATAFILES.

You cannot use this statement to drop a tablespace group. However, if *tablespace* is the only tablespace in a tablespace group, then Oracle Database removes the tablespace group from the data dictionary as well.

Restrictions on Dropping Tablespaces

Dropping tablespaces is subject to the following restrictions:

- You cannot drop a tablespace that contains a domain index or any objects created by a domain index.

- You cannot drop an undo tablespace if it is being used by any instance or if it contains any undo data needed to roll back uncommitted transactions.
- You cannot drop a tablespace that has been designated as the default tablespace for the database. You must first reassign another tablespace as the default tablespace and then drop the old default tablespace.
- You cannot drop a temporary tablespace if it is part of the database default temporary tablespace group. You must first remove the tablespace from the database default temporary tablespace group and then drop it.
- You cannot drop a temporary tablespace if it contains segments that are in use by existing sessions. In this case, no error is raised. The database waits until there are no segments in use by existing sessions and then drops the tablespace.
- You cannot drop a tablespace, even with the `INCLUDING CONTENTS` and `CASCADE CONSTRAINTS` clauses, if doing so would disable a primary key or unique constraint in another tablespace. For example, if the tablespace being dropped contains a primary key index, but the primary key column itself is in a different tablespace, then you cannot drop the tablespace until you have manually disabled the primary key constraint in the other tablespace.

See Also

Oracle Database Data Cartridge Developer's Guide and *Oracle Database Concepts* for more information on domain indexes

{ DROP | KEEP } QUOTA

Specify `DROP QUOTA` to drop all user quotas for the tablespace. Specify `KEEP QUOTA` to retain all user quotas for the tablespace. The default is `KEEP QUOTA`.

You can view all user quotas for a tablespace by querying the `DBA_TS_QUOTAS` data dictionary view.

INCLUDING CONTENTS

Specify `INCLUDING CONTENTS` to drop all the contents of the tablespace, including those of shadow tablespaces that store lost write protection updates. You must specify this clause to drop a tablespace that contains any database objects. If you omit this clause, and the tablespace is not empty, then the database returns an error and does not drop the tablespace.

`DROP TABLESPACE` fails, even if you specify `INCLUDING CONTENTS`, if the tablespace contains some, but not all, of the partitions or subpartitions of a single table. If all the partitions or subpartitions of a partitioned table reside in *tablespace*, then `DROP TABLESPACE ... INCLUDING CONTENTS` drops *tablespace*, as well as any associated index segments, LOB data and index segments, and nested table data and index segments of *table* in other tablespace(s).

For a partitioned index-organized table, if all the primary key index segments are in this tablespace, then this clause will also drop any overflow segments that exist in other tablespaces, as well as any associated mapping table in other tablespaces. If some of the primary key index segments are *not* in this tablespace, then the statement will fail. In that case, before you can drop the tablespace, you must use `ALTER TABLE ... MOVE PARTITION` to move those primary key index segments into this tablespace, drop the partitions whose overflow data segments are not in this tablespace, and drop the partitioned index-organized table.

If the tablespace contains a master table of a materialized view, then the database invalidates the materialized view.

If the tablespace contains a materialized view log, then the database drops the log and any other direct-path INSERT refresh information associated with the table.

AND DATAFILES

When you specify `INCLUDING CONTENTS`, the `AND DATAFILES` clause lets you instruct the database to delete the associated operating system files as well. Oracle Database writes a message to the alert log for each operating system file deleted. This clause is not needed for Oracle Managed Files, because they are removed from the system even if you do not specify `AND DATAFILES`.

KEEP DATAFILES

When you specify `INCLUDING CONTENTS`, the `KEEP DATAFILES` clause lets you instruct the database to leave untouched the associated operating system files, including Oracle Managed Files. You must specify this clause if you are using Oracle Managed Files and you do not want the associated operating system files removed by the `INCLUDING CONTENTS` clause.

CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` to drop all referential integrity constraints from tables outside *tablespace* that refer to primary and unique keys of tables inside *tablespace*. If you omit this clause and such referential integrity constraints exist, then Oracle Database returns an error and does not drop the tablespace.

Examples

Dropping a Tablespace: Example

The following statement drops the `tbs_01` tablespace and drops all referential integrity constraints that refer to primary and unique keys inside `tbs_01`:

```
DROP TABLESPACE tbs_01
    INCLUDING CONTENTS
    CASCADE CONSTRAINTS;
```

Dropping a Shadow Tablespace: Example

The following statement tries to move the tracked data in the shadow tablespace to another shadow tablespace. This only works if there are shadow tablespaces in the PDB with enough free space.

```
DROP TABLESPACE <shadow_tablespace_name>
```

The following statement drops the shadow tablespace and all its contents. All the tracking data is lost.

Dropping Shadow Tablespace Including Contents: Example

```
DROP TABLESPACE <shadow_tablespace_name>
    INCLUDING CONTENTS
```

Deleting Operating System Files: Example

The following example drops the `tbs_02` tablespace and deletes all associated operating system data files:

```
DROP TABLESPACE tbs_02
    INCLUDING CONTENTS AND DATAFILES;
```

DROP TABLESPACE SET

Note

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator's Guide*.

Purpose

Use the DROP TABLESPACE SET statement to drop a tablespace set from a shardgroup.

When you drop a tablespace set, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace set.

See Also

[CREATE TABLESPACE SET](#) and [ALTER TABLESPACE SET](#)

Prerequisites

You must be connected to a shard catalog database as an SDB user.

You must have the DROP TABLESPACE system privilege. You cannot drop a tablespace set if its tablespaces contain any rollback segments holding active transactions.

Syntax

drop_tablespace_set::=

Semantics

tablespace_set

Specify the name of the tablespace set to be dropped.

INCLUDING CONTENTS

This clause lets you specify how the database manages objects and datafiles associated with the tablespaces in the tablespace set during the drop operation. The INCLUDING CONTENTS clause has the same semantics here as for the DROP TABLESPACE statement. See [INCLUDING CONTENTS](#) for the full semantics of this clause.

Examples

Dropping a Tablespace Set: Example

The following statement drops the tablespace set ts1:

```
DROP TABLESPACE SET ts1;
```

DROP TRIGGER

Purpose

Triggers are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping triggers.

Use the DROP TRIGGER statement to remove a database trigger from the database.

See Also

[CREATE TRIGGER](#) and [ALTER TRIGGER](#)

Prerequisites

The trigger must be in your own schema or you must have the DROP ANY TRIGGER system privilege. To drop a trigger on DATABASE in another user's schema, you must also have the ADMINISTER DATABASE TRIGGER system privilege.

Syntax

drop_trigger ::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the trigger. If you omit *schema*, then Oracle Database assumes the trigger is in your own schema.

trigger

Specify the name of the trigger to be dropped. Oracle Database removes it from the database and does not fire it again.

Examples

Dropping a Trigger: Example

The following statement drops the salary_check trigger in the schema hr:

```
DROP TRIGGER hr.salary_check;
```

DROP TYPE

Purpose

Object types are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping object types.

Use the DROP TYPE statement to drop the specification and body of an object type, a varray, or a nested table type.

Prerequisites

The object type, varray, or nested table type must be in your own schema or you must have the DROP ANY TYPE system privilege.

Syntax

drop_type::=

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

Semantics

schema

Specify the schema containing the type. If you omit *schema*, then Oracle Database assumes the type is in your own schema.

type_name

Specify the name of the object, varray, or nested table type to be dropped. You can drop only types with no type or table dependencies. This includes tables in the recycle bin.

When you drop a type, any dependent objects such as subtypes are not placed in the recycle bin and any former dependent objects in the recycle bin are purged.

If *type_name* is a supertype, then this statement will fail unless you also specify FORCE. If you specify FORCE, then the database invalidates all subtypes depending on this supertype.

If *type_name* is a statistics type, then this statement will fail unless you also specify **FORCE**. If you specify **FORCE**, then the database first disassociates all objects that are associated with *type_name* and then drops *type_name*.

See Also

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics types

If *type_name* is an object type that has been associated with a statistics type, then the database first attempts to disassociate *type_name* from the statistics type and then drops *type_name*. However, if statistics have been collected using the statistics type, then the database will be unable to disassociate *type_name* from the statistics type, and this statement will fail.

If *type_name* is an implementation type for an indextype, then the indextype will be marked **INVALID**.

If *type_name* has a public synonym defined on it, then the database will also drop the synonym.

Unless you specify **FORCE**, you can drop only object types, nested tables, or varray types that are standalone schema objects with no dependencies. This is the default behavior.

See Also

[CREATE INDEXTYPE](#)

FORCE

Specify **FORCE** to drop the type even if it has dependent database objects. Oracle Database marks **UNUSED** all columns dependent on the type to be dropped, and those columns become inaccessible.

Note

Oracle does not recommend that you specify **FORCE** to drop object types with dependencies. These include dependent tables in the recycle bin. This operation is not recoverable and could cause the data in the dependent tables or columns to become inaccessible.

Refer to *Managing Tables* .

VALIDATE

If you specify **VALIDATE** when dropping a type, then Oracle Database checks for stored instances of this type within substitutable columns of any of its supertypes. If no such instances are found, then the database completes the drop operation.

This clause is meaningful only for subtypes. Oracle recommends the use of this option to safely drop subtypes that do not have any explicit type or table dependencies.

Examples

Dropping an Object Type: Example

The following statement removes object type `person_t`. See *Oracle Database PL/SQL Language Reference* for the example that creates this object type. Any columns that are dependent on `person_t` are marked `UNUSED` and become inaccessible.

```
DROP TYPE person_t FORCE;
```

DROP TYPE BODY

Purpose

Object types are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping object types.

Use the `DROP TYPE BODY` statement to drop the body of an object type, varray, or nested table type. When you drop a type body, the object type specification still exists, and you can re-create the type body. Prior to re-creating the body, you can still use the object type, although you cannot call the member functions.

Prerequisites

The object type body must be in your own schema or you must have the `DROP ANY TYPE` system privilege.

Syntax

drop_type_body::=

Semantics

IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

schema

Specify the schema containing the object type. If you omit *schema*, then Oracle Database assumes the object type is in your own schema.

type_name

Specify the name of the object type body to be dropped.

Restriction on Dropping Type Bodies

You can drop a type body only if it has no type or table dependencies.

Examples

Dropping an Object Type Body: Example

The following statement removes object type body data_typ1. See *Oracle Database PL/SQL Language Reference* for the example that creates this object type.

```
DROP TYPE BODY data_typ1;
```

DROP USER

Purpose

Use the DROP USER statement to remove a database user and optionally remove the user's objects.

In an Oracle Automatic Storage Management (Oracle ASM) cluster, a user authenticated AS SYSASM can use this clause to remove a user from the password file that is local to the Oracle ASM instance of the current node.

When you drop a user, the database drops all of that user's schema objects from the recycle bin.

Note

Do not attempt to drop the users SYS or SYSTEM. Doing so will corrupt your database.

See Also

[CREATE USER](#) and [ALTER USER](#) for information on creating and modifying a user

Prerequisites

You must have the DROP USER system privilege. In an Oracle ASM cluster, you must be authenticated AS SYSASM.

Syntax

drop_user::=

Semantics

IF EXISTS

Specify IF EXISTS to drop an existing object.

Specifying IF NOT EXISTS with DROP results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

user

Specify the user to be dropped. Oracle Database does not drop users whose schemas contain objects unless you specify **CASCADE** or unless you first explicitly drop the user's objects.

Restriction on Dropping Users

You cannot drop a user whose schema contains a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback data archive.

CASCADE

Specify **CASCADE** to drop all objects in the user's schema before dropping the user. You must specify this clause to drop a user whose schema contains any objects.

- If the user's schema contains tables, then Oracle Database drops the tables and automatically drops any referential integrity constraints on tables in other schemas that refer to primary and unique keys on these tables.
- If this clause results in tables being dropped, then the database also drops all domain indexes created on columns of those tables and invokes appropriate drop routines.

See Also

Oracle Database Data Cartridge Developer's Guide for more information on these routines

- Oracle Database invalidates, but does not drop, the following objects in other schemas:
 - Views or synonyms for objects in the dropped user's schema
 - Stored procedures, functions, or packages that query objects in the dropped user's schema
- Oracle Database does not drop materialized views in other schemas that are based on tables in the dropped user's schema. However, because the base tables no longer exist, the materialized views in the other schemas can no longer be refreshed.
- Oracle Database drops all triggers in the user's schema.
- Oracle Database does not drop roles created by the user.
- Oracle Database drops all domains in the user's schemas. The database will issue **DROP DOMAIN FORCE** for all domains the user owns.

Note

Oracle Database also drops with **FORCE** all types owned by the user. See the [FORCE](#) keyword of [DROP TYPE](#).

Examples

Dropping a Database User: Example

If user Sidney's schema contains no objects, then you can drop `sidney` by issuing the statement:

```
DROP USER sidney;
```

If Sidney's schema contains objects, then you must use the `CASCADE` clause to drop sidney and the objects:

```
DROP USER sidney CASCADE;
```

DROP VIEW

Purpose

Use the `DROP VIEW` statement to remove a view or an object view from the database. You can change the definition of a view by dropping and re-creating it.

When you drop a view, data grants on the object are also dropped.

See Also

[CREATE VIEW](#) and [ALTER VIEW](#) for information on creating and modifying a view

Prerequisites

The view must be in your own schema or you must have the `DROP ANY VIEW` system privilege.

Syntax

drop_view::=

Semantics

IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

schema

Specify the schema containing the view. If you omit *schema*, then Oracle Database assumes the view is in your own schema.

view

Specify the name of the view to be dropped.

Oracle Database does not drop views, materialized views, and synonyms that are dependent on the view but marks them `INVALID`. You can drop them or redefine views and synonyms, or you can define other views in such a way that the invalid views and synonyms become valid again.

If any subviews have been defined on *view*, then the database invalidates the subviews as well. To determine whether the view has any subviews, query the SUPERVIEW_NAME column of the USER_, ALL_, or DBA_VIEWS data dictionary views.

📘 See Also

- [CREATE TABLE](#) and [CREATE SYNONYM](#)
- [ALTER MATERIALIZED VIEW](#) for information on revalidating invalid materialized views

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the view to be dropped. If you omit this clause, and such constraints exist, then the DROP statement fails.

Examples

Dropping a View: Example

The following statement drops the emp_view view, which was created in "[Creating a View: Example](#)":

```
DROP VIEW emp_view;
```

EXPLAIN PLAN

Purpose

Use the EXPLAIN PLAN statement to determine the execution plan Oracle Database follows to execute a specified SQL statement. This statement inserts a row describing each step of the execution plan into a specified table. You can also issue the EXPLAIN PLAN statement as part of the SQL trace facility.

This statement also determines the cost of executing the statement. If any domain indexes are defined on the table, then user-defined CPU and I/O costs will also be inserted.

The definition of a sample output table PLAN_TABLE is available in a SQL script on your distribution media. Your output table must have the same column names and data types as this table. The common name of this script is UTLXPLAN.SQL. The exact name and location depend on your operating system.

Oracle Database provides information on cached cursors through several dynamic performance views:

- For information on the work areas used by SQL cursors, query V\$SQL_WORKAREA.
- For information on the execution plan for a cached cursor, query V\$SQL_PLAN.
- For execution statistics at each step or operation of an execution plan of cached cursors (for example, number of produced rows, number of blocks read), query V\$SQL_PLAN_STATISTICS.
- For a selective precomputed join of the preceding three views, query V\$SQL_PLAN_STATISTICS_ALL.

- Execution statistics at each step or operation of an execution plan of cached cursors are displayed in V\$SQL_PLAN_MONITOR if the statement execution is monitored. You can force monitoring using the MONITOR hint.

See Also

- Oracle Database SQL Tuning Guide* for information on the output of EXPLAIN PLAN, how to use the SQL trace facility, and how to generate and interpret execution plans
- Oracle Database Reference* for information on dynamic performance views

Prerequisites

To issue an EXPLAIN PLAN statement, you must have the privileges necessary to insert rows into an existing output table that you specify to hold the execution plan.

You must also have the privileges necessary to execute the SQL statement for which you are determining the execution plan. If the SQL statement accesses a view, then you must have privileges to access any tables and views on which the view is based. If the view is based on another view that is based on a table, then you must have privileges to access both the other view and its underlying table.

To examine the execution plan produced by an EXPLAIN PLAN statement, you must have the privileges necessary to query the output table.

The EXPLAIN PLAN statement is a data manipulation language (DML) statement, rather than a data definition language (DDL) statement. Therefore, Oracle Database does not implicitly commit the changes made by an EXPLAIN PLAN statement. If you want to keep the rows generated by an EXPLAIN PLAN statement in the output table, then you must commit the transaction containing the statement.

See Also

[INSERT](#) and [SELECT](#) for information on the privileges you need to populate and query the plan table

Syntax

explain_plan::=

Semantics

SET STATEMENT_ID Clause

Specify a value for the STATEMENT_ID column for the rows of the execution plan in the output table. You can then use this value to identify these rows among others in the output table. Be sure to specify a STATEMENT_ID value if your output table contains rows from many execution plans. If you omit this clause, then the STATEMENT_ID value defaults to null.

INTO *table* Clause

Specify the name of the output table, and optionally its schema and database. This table must exist before you use the EXPLAIN PLAN statement.

If you omit *schema*, then the database assumes the table is in your own schema.

The *dblink* can be a complete or partial name of a database link to a remote Oracle Database where the output table is located. You can specify a remote output table only if you are using Oracle Database distributed functionality. If you omit *dblink*, then the database assumes the table is on your local database. See "[References to Objects in Remote Databases](#)" for information on referring to database links.

If you omit INTO altogether, then the database assumes an output table named PLAN_TABLE in your own schema on your local database.

FOR *statement* Clause

Specify a SELECT, INSERT, UPDATE, DELETE, MERGE, CREATE TABLE, CREATE INDEX, or ALTER INDEX ... REBUILD statement for which the execution plan is generated.

Notes on EXPLAIN PLAN

The following notes apply to EXPLAIN PLAN:

- If *statement* includes the *parallel_clause*, then the resulting execution plan will indicate parallel execution. However, EXPLAIN PLAN actually inserts the statement into the plan table, so that the parallel DML statement you submit is no longer the first DML statement in the transaction. This violates the Oracle Database restriction of one parallel DML statement in a single transaction, and the statement will be executed serially. To maintain parallel execution of the statements, you must commit or roll back the EXPLAIN PLAN statement, and then submit the parallel DML statement.
- To determine the execution plan for an operation on a temporary table, EXPLAIN PLAN must be run from the same session, because the data in temporary tables is session specific.

Examples

EXPLAIN PLAN Examples

The following statement determines the execution plan and cost for an UPDATE statement and inserts rows describing the execution plan into the specified plan_table table with the STATEMENT_ID value of 'Raise in Tokyo':

```
EXPLAIN PLAN
  SET STATEMENT_ID = 'Raise in Tokyo'
  INTO plan_table
  FOR UPDATE employees
    SET salary = salary * 1.10
    WHERE department_id =
```

```
(SELECT department_id FROM departments
WHERE location_id = 1700);
```

The following SELECT statement queries the plan_table table and returns the execution plan and the cost:

```
SELECT id, LPAD(' ', 2*(LEVEL-1))||operation operation, options,
       object_name, object_alias, position
FROM plan_table
START WITH id = 0 AND statement_id = 'Raise in Tokyo'
CONNECT BY PRIOR id = parent_id AND statement_id = 'Raise in Tokyo'
ORDER BY id;
```

The query returns this execution plan:

ID	OPERATION	OPTIONS	OBJECT_NAME	OBJECT_ALIAS	POSITION
0	UPDATE STATEMENT				4
1	UPDATE		EMPLOYEES		1
2	INDEX	RANGE SCAN	EMP_DEPARTMENT_IX	EMPLOYEES@UPD\$1	1
3	TABLE ACCESS	BY INDEX ROWID	DEPARTMENTS	DEPARTMENTS@SEL\$1	1
4	INDEX	RANGE SCAN	DEPT_LOCATION_IX	DEPARTMENTS@SEL\$1	1

The value in the POSITION column of the first row shows that the statement has a cost of 4.

EXPLAIN PLAN: Partitioned Example

The sample table sh.sales is partitioned on the time_id column. Partition sales_q3_2000 contains time values less than Oct. 1, 2000, and there is a local index sales_time_bix on the time_id column.

Consider the query:

```
EXPLAIN PLAN FOR
SELECT * FROM sales
WHERE time_id BETWEEN :h AND '01-OCT-2000';
```

where :h represents an already declared bind variable. EXPLAIN PLAN executes this query with PLAN_TABLE as the output table. The basic execution plan, including partitioning information, is obtained with the following query:

```
SELECT operation, options, partition_start, partition_stop,
       partition_id
FROM plan_table;
```

FLASHBACK DATABASE

Purpose

Use the FLASHBACK DATABASE statement to return the database to a past time or system change number (SCN). This statement provides a fast alternative to performing incomplete database recovery.

Following a FLASHBACK DATABASE operation, in order to have write access to the flashed back database, you must reopen it with an ALTER DATABASE OPEN RESETLOGS statement.

① See Also

Oracle Database Backup and Recovery User's Guide for more information on FLASHBACK DATABASE

Prerequisites

You must have the SYSDBA, SYSBACKUP, or SYSDG system privilege.

If you are connected to a multitenant container database (CDB):

- To flash back a CDB, you must be connected to the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To flash back a PDB you must be connected to the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or you must be connected to the PDB you want to flash back and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

A fast recovery area must have been prepared for the database. The database must have been put in FLASHBACK mode with an ALTER DATABASE FLASHBACK ON statement unless you are flashing the database back to a guaranteed restore point. The database must be mounted but not open.

In addition:

- The database must run in ARCHIVELOG mode.
- The database must be mounted, but not open, with a current control file. The control file cannot be a backup or re-created. When the database control file is restored from backup or re-created, all existing flashback log information is discarded.
- The database must contain no online tablespaces for which flashback functionality was disabled with the SQL statement ALTER TABLESPACE ... FLASHBACK OFF.

① See Also

- *Oracle Database Backup and Recovery User's Guide* and the ALTER DATABASE ... [flashback mode clause](#) for information on putting the database in FLASHBACK mode
- [CREATE RESTORE POINT](#) for information on restore points and guaranteed restore points

Syntax

flashback_database::=

Semantics

When you issue a FLASHBACK DATABASE statement, Oracle Database first verifies that all required archived and online redo logs are available. If they are available, then it reverts all currently online data files in the database to the SCN or time specified in this statement.

- The amount of Flashback data retained in the database is controlled by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter and the size of the fast recovery area. You can determine how far back you can flash back the database by querying the `V$FLASHBACK_DATABASE_LOG` view.
- If insufficient data remains in the database to perform the flashback, then you can use standard recovery procedures to recover the database to a past point in time.
- If insufficient data remains for a set of data files, then the database returns an error. In this case, you can take those data files offline and reissue the statement to revert the remainder of the database. You can then attempt to recover the offline data files using standard recovery procedures.

See Also

Oracle Database Backup and Recovery User's Guide for more information on recovering data files

STANDBY

Specify `STANDBY` to revert the standby database to an earlier SCN or time. If the database is not a standby database, then the database returns an error. If you omit this clause, then *database* can be either a primary or a standby database.

See Also

Oracle Data Guard Concepts and Administration for information on how you can use FLASHBACK DATABASE on a standby database to achieve different delays

PLUGGABLE

Specify PLUGGABLE to flash back a PDB. You must specify this clause whether the current container is the root or the PDB you want to flash back.

Restrictions on Flashing Back a PDB

- You cannot flash back a proxy PDB.
- If the CDB is in shared undo mode, then you can only flash back a PDB to a clean PDB restore point. Refer to the [CLEAN](#) clause of CREATE RESTORE POINT for more information.

database

If you are flashing back a CDB, then you can optionally specify the name of the database to be flashed back. If you omit *database*, then Oracle Database flashes back the database identified by the value of the initialization parameter DB_NAME.

If you are flashing back a PDB and the current container is the root, then use *database* to specify the name of the PDB to be flashed back. If you are flashing back a PDB and the current container is that PDB, then you can optionally use *database* to specify the PDB name.

TO SCN Clause

Specify a system change number (SCN):

- TO SCN reverts the database back to its state at the specified SCN.
- TO BEFORE SCN reverts the database back to its state at the system change number just preceding the specified SCN.

You can determine the current SCN by querying the CURRENT_SCN column of the V\$DATABASE view. This in turn lets you save the SCN to a spool file, for example, before running a high-risk batch job.

TO TIMESTAMP Clause

Specify a valid datetime expression.

- TO TIMESTAMP reverts the database back to its state at the specified timestamp.
- TO BEFORE TIMESTAMP reverts the database back to its state one second before the specified timestamp.

You can represent the timestamp as an offset from a determinate value, such as SYSDATE, or as an absolute system timestamp.

TO RESTORE POINT Clause

Specify this clause to flash back the database to the specified restore point. If you have not enabled flashback database, then this is the only clause you can specify in this FLASHBACK DATABASE statement. If the database is not in FLASHBACK mode, as described in the "Prerequisites" section above, then this is the only clause you can specify for this statement.

RESETLOGS

Specify TO BEFORE RESETLOGS to flash the database back to just before the last resetlogs operation (ALTER DATABASE OPEN RESETLOGS).

See Also

Oracle Database Backup and Recovery User's Guide for more information about this clause

Examples

Assuming that you have prepared a fast recovery area for the database and enabled media recovery, enable database FLASHBACK mode and open the database with the following statements:

```
STARTUP MOUNT
ALTER DATABASE FLASHBACK ON;
ALTER DATABASE OPEN;
```

With your database open for at least a day, you can flash back the database one day with the following statements:

```
SHUTDOWN DATABASE
STARTUP MOUNT
FLASHBACK DATABASE TO TIMESTAMP SYSDATE-1;
```

FLASHBACK TABLE

Purpose

Use the FLASHBACK TABLE statement to restore an earlier state of a table in the event of human or application error. The time in the past to which the table can be flashed back is dependent on the amount of undo data in the system. Also, Oracle Database cannot restore a table to an earlier state across any DDL operations that change the structure of the table.

Note

Oracle strongly recommends that you run your database in automatic undo mode by leaving the UNDO_MANAGEMENT initialization parameter set to AUTO, which is the default. In addition, set the UNDO_RETENTION initialization parameter to an interval large enough to include the oldest data you anticipate needing. For more information refer to the documentation on the UNDO_MANAGEMENT and UNDO_RETENTION initialization parameters.

You cannot roll back a FLASHBACK TABLE statement. However, you can issue another FLASHBACK TABLE statement and specify a time just prior to the current time. Therefore, it is advisable to record the current SCN before issuing a FLASHBACK TABLE clause.

See Also

- To set the UNDO_RETENTION initialization parameter, see [Setting the Minimum Undo Retention Period](#)
- [FLASHBACK DATABASE](#) for information on reverting the entire database to an earlier version
- the [flashback query clause](#) of SELECT for information on retrieving past data from a table
- *Oracle Database Backup and Recovery User's Guide* for additional information on using the FLASHBACK TABLE statement

Prerequisites

To flash back a table to an earlier SCN or timestamp, you must have either the FLASHBACK object privilege on the table or the FLASHBACK ANY TABLE system privilege. In addition, you must have the READ or SELECT object privilege on the table, and you must have the INSERT, DELETE, and ALTER object privileges on the table.

Row movement must be enabled for all tables in the Flashback list unless you are flashing back the table TO BEFORE DROP. That operation is called a **flashback drop** operation, and it uses dropped data in the recycle bin rather than undo data. Refer to [row movement clause](#) for information on enabling row movement.

To flash back a table to a restore point, you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role.

To flash back a table to before a DROP TABLE operation, you need only the privileges necessary to drop the table.

Syntax

flashback table::=

**Semantics**

During an Oracle Flashback Table operation, Oracle Database acquires exclusive DML locks on all the tables specified in the Flashback list. These locks prevent any operations on the tables while they are reverting to their earlier state.

The Flashback Table operation is executed in a single transaction, regardless of the number of tables specified in the Flashback list. Either all of the tables revert to the earlier state or none of them do. If the Flashback Table operation fails on any table, then the entire statement fails.

At the completion of the Flashback Table operation, the data in *table* is consistent with *table* at the earlier time. However, FLASHBACK TABLE TO SCN or TIMESTAMP does not preserve rowids, and FLASHBACK TABLE TO BEFORE DROP does not recover referential constraints.

Oracle Database does not revert statistics associated with *table* to their earlier form. Indexes on *table* that exist currently are reverted and reflect the state of the table at the Flashback point. If the index exists now but did not yet exist at the Flashback point, then the database updates the index to reflect the state of the table at the Flashback point. However, indexes that were dropped during the interval between the Flashback point and the current time are not restored.

schema

Specify the schema containing the table. If you omit *schema*, then the database assumes the table is in your own schema.

table

Specify the name of one or more tables containing data you want to revert to an earlier version.

Restrictions on Flashing Back Tables

This statement is subject to the following restrictions:

- Flashback Table operations are not valid for the following type objects: tables that are part of a cluster, child tables using reference partitioning, materialized views, Advanced Queuing (AQ) tables, static data dictionary tables, system tables, remote tables, object tables, nested tables, or individual table partitions or subpartitions.
- The following DDL operations change the structure of a table, so that you cannot subsequently use the TO SCN or TO TIMESTAMP clause to flash the table back to a time preceding the operation: upgrading, moving, or truncating a table; adding a constraint to a table, adding a table to a cluster; modifying or dropping a column; changing a column encryption key; adding, dropping, merging, splitting, coalescing, or truncating a partition or subpartition (with the exception of adding a range partition).

TO SCN Clause

Specify the system change number (SCN) corresponding to the point in time to which you want to return the table. The *expr* must evaluate to a number representing a valid SCN.

TO TIMESTAMP Clause

Specify a timestamp value corresponding to the point in time to which you want to return the table. The *expr* must evaluate to a valid timestamp in the past. The table will be flashed back to a time within approximately 3 seconds of the specified timestamp.

TO RESTORE POINT Clause

Specify a restore point to which you want to flash back the table. The restore point must already have been created.

① See Also

[CREATE RESTORE POINT](#) for information on creating restore points

ENABLE | DISABLE TRIGGERS

By default, Oracle Database disables all enabled triggers defined on *table* during the Flashback Table operation and then reenables them after the Flashback Table operation is complete. Specify **ENABLE TRIGGERS** if you want to override this default behavior and keep the triggers enabled during the Flashback process.

This clause affects only those database triggers defined on *table* that are already enabled. To enable currently disabled triggers selectively, use the **ALTER TABLE ... enable_disable_clause** before you issue the **FLASHBACK TABLE** statement with the **ENABLE TRIGGERS** clause.

TO BEFORE DROP Clause

Use this clause to retrieve from the recycle bin a table that has been dropped, along with all possible dependent objects. The table must have resided in a locally managed tablespace other than the **SYSTEM** tablespace.

① See Also

- *Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin
- [PURGE](#) for information on removing objects permanently from the recycle bin

You can specify either the original user-specified name of the table or the system-generated name Oracle Database assigned to the object when it was dropped.

- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database retrieves that specified object.

To see the contents of your recycle bin, query the **USER_RECYCLEBIN** data dictionary view. You can use the **RECYCLEBIN** synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;  
SELECT * FROM USER_RECYCLEBIN;
```

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database retrieves the object that was moved to the recycle bin most recently. If you want to retrieve an older version of the table, then do one of these things:
 - Specify the system-generated recycle bin name of the table you want to retrieve.
 - Issue additional **FLASHBACK TABLE ... TO BEFORE DROP** statements until you retrieve the table you want.

Oracle Database attempts to preserve the original table name. If a new table of the same name has been created in the same schema since the original table was dropped, then the database returns an error unless you also specify the **RENAME TO** clause.

RENAME TO Clause

Use this clause to specify a new name for the table being retrieved from the recycle bin.

Notes on Flashing Back Dropped Tables

The following notes apply to flashing back dropped tables:

- Oracle Database retrieves all indexes defined on the table retrieved from the recycle bin except for bitmap join indexes and domain indexes. (Bitmap join indexes and domain indexes are not put in the recycle bin during a DROP TABLE operation, so cannot be retrieved.)
- The database also retrieves all triggers and constraints defined on the table except for referential integrity constraints that reference other tables.

The retrieved indexes, triggers, and constraints have recycle bin names. Therefore it is advisable to query the USER_RECYCLEBIN view before issuing a FLASHBACK TABLE ... TO BEFORE DROP statement so that you can rename the retrieved triggers and constraints to more usable names.

- When you drop a table, all materialized view logs defined on the table are also dropped but are not placed in the recycle bin. Therefore, the materialized view logs cannot be flashed back along with the table.
- When you drop a table, any indexes on the table are dropped and put into the recycle bin along with the table. If subsequent space pressures arise, then the database reclaims space from the recycle bin by first purging indexes. In this case, when you flash back the table, you may not get back all of the indexes that were defined on the table.
- You cannot flash back a table if it has been purged, either by a user or by Oracle Database as a result of some space reclamation operation.

Examples

Restoring a Table to an Earlier State: Examples

The examples below create a new table, employees_test, with row movement enabled, update values within the new table, and issue the FLASHBACK TABLE statement.

Create table employees_test, with row movement enabled, from table employees of the sample hr schema:

```
CREATE TABLE employees_test
  AS SELECT * FROM employees;
```

As a benchmark, list those salaries less than 2500:

```
SELECT salary
  FROM employees_test
 WHERE salary < 2500;
```

```
      SALARY
-----
      2400
      2200
      2100
      2400
      2200
```

Note

To allow time for the SCN to propagate to the mapping table used by the FLASHBACK TABLE statement, wait a minimum of 5 minutes prior to issuing the following statement. This wait would not be necessary if a previously existing table were being used in this example.

Enable row movement for the table:

```
ALTER TABLE employees_test
  ENABLE ROW MOVEMENT;
```

Issue a 10% salary increase to those employees earning less than 2500:

```
UPDATE employees_test
  SET salary = salary * 1.1
  WHERE salary < 2500;
```

```
5 rows updated.
COMMIT;
```

As a second benchmark, list those salaries that remain less than 2500 following the 10% increase:

```
SELECT salary
  FROM employees_test
  WHERE salary < 2500;
```

```
      SALARY
-----
        2420
        2310
        2420
```

Restore the table employees_test to its state prior to the current system time. The unrealistic duration of 1 minute is used so that you can test this series of examples quickly. Under normal circumstances a much greater interval would have elapsed.

```
FLASHBACK TABLE employees_test
  TO TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' minute);
```

List those salaries less than 2500. After the FLASHBACK TABLE statement issued above, this list should match the list in the first benchmark.

```
SELECT salary
  FROM employees_test
  WHERE salary < 2500;
```

```
      SALARY
-----
        2400
        2200
        2100
        2400
        2200
```

Retrieving a Dropped Table: Example

If you accidentally drop the `pm.print_media` table and want to retrieve it, then issue the following statement:

```
FLASHBACK TABLE print_media TO BEFORE DROP;
```

If another `print_media` table has been created in the `pm` schema, then use the `RENAME TO` clause to rename the retrieved table:

```
FLASHBACK TABLE print_media TO BEFORE DROP RENAME TO print_media_old;
```

If you know that the `employees` table has been dropped multiple times, and you want to retrieve the oldest version, then query the `USER_RECYCLEBIN` table to determine the system-generated name, and then use that name in the `FLASHBACK TABLE` statement. (System-generated names in your database will differ from those shown here.)

```
SELECT object_name, droptime FROM user_recyclebin
       WHERE original_name = 'PRINT_MEDIA';
```

OBJECT_NAME	DROPTIME
RB\$\$\$45703\$TABLE\$0	2003-06-03:15:26:39
RB\$\$\$45704\$TABLE\$0	2003-06-12:12:27:27
RB\$\$\$45705\$TABLE\$0	2003-07-08:09:28:01

GRANT

Purpose

Use the `GRANT` statement to grant:

- Administrative privileges to users only (not to roles). [Table 18-1](#)
Refer to the *Database Security Guide* for more information about administrative privileges *Managing Administrative Privileges*
- System privileges to users and roles. [Table 18-2](#)
Note that ANY system privileges, for example, `SELECT ANY TABLE`, will not work on SYS objects or other dictionary objects.
- Schema privileges to users and roles. [Table 18-3](#)
- Roles to users, roles, and program units. The granted roles can be either user-defined (local or external) or predefined. For a list of predefined roles, refer to *Oracle AI Database Security Guide*.
- Object privileges for a particular object to users and roles. [Table 18-4](#)

Note

Global roles (created with `IDENTIFIED GLOBALLY`) are granted through enterprise roles and cannot be granted using the `GRANT` statement.

Notes on Authorizing Database Users

You can authorize database users through means other than the database and the `GRANT` statement.

- Many database privileges are granted through supplied PL/SQL and Java packages. For information on those privileges, refer to the documentation for the appropriate package.
- Some operating systems have facilities that let you grant roles to the database users with the initialization parameter `OS_ROLES`. If you choose to grant roles to users through operating system facilities, then you cannot also grant roles to users with the `GRANT` statement, although you can use the `GRANT` statement to grant system privileges to users and system privileges and roles to other roles.

Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to grant the administrative privileges SYSASM, SYSOPER, and SYSDBA to a user in the Oracle ASM password file of the current node.

Note on Editionable Objects

A `GRANT` operation to grant object privileges on an editionable object actualizes the object in the current edition. See *Oracle AI Database Development Guide* for more information about editions and editionable objects.

① See Also

- [CREATE USER](#) and [CREATE ROLE](#) for definitions of local, global, and external privileges
- *Oracle AI Database Security Guide* for information about other authorization methods and for information about privileges
- [REVOKE](#) for information on revoking grants

Prerequisites

To grant a **system privilege**, one of the following conditions must be met:

- You must have been granted the `GRANT ANY PRIVILEGE` system privilege. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted does not have the privilege unless the role is enabled in user's session.
- You must have been granted the system privilege with the `ADMIN OPTION`. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted has the privilege regardless whether the role is enabled in the user's session.

To grant a **role to a user or another role**, you must have been directly granted the role with the `ADMIN OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in your own schema**, you must have been directly granted the role with either the `ADMIN OPTION` or the `DELEGATE OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in another user's schema**, you must be the user `SYS` and the role must have been created by the schema owner or directly granted to the schema owner.

To grant an **object privilege on a user**, by specifying the `ON USER` clause of the *on_object_clause*, you must be the user on whom the privilege is granted, or you must have been granted the object privilege on that user with the `WITH GRANT OPTION`, or you must have been granted the `GRANT ANY OBJECT PRIVILEGE` system privilege. If you can grant an object privilege on a user only because you have the `GRANT ANY OBJECT PRIVILEGE`, then the `GRANTOR`

column of the *_TAB_PRIVS views displays the user on whom the privilege is granted rather than the user who issued the GRANT statement.

To grant an **object privilege on all other types of objects**, you must own the object, or the owner of the object must have granted you the object privileges with the WITH GRANT OPTION, or you must have been granted the GRANT ANY OBJECT PRIVILEGE system privilege. If you have the GRANT ANY OBJECT PRIVILEGE, then you can grant the object privilege only if the object owner could have granted the same object privilege. In this case, the GRANTOR column of the *_TAB_PRIVS views displays the object owner rather than the user who issued the GRANT statement.

You can revoke privileges on an object if you have the GRANT ANY object privilege. This does not apply to dictionary protected schemas. The ANY keyword in reference to a system privilege means that the user can perform the privilege on any objects owned by any user except for SYS.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

Syntax

grant::=

[\(grant_system_privileges::=, grant_schema_privileges::=, grant_object_privileges::=, grant_roles_to_programs::=\)](#)

grant_system_privileges::=

[\(grantee_clause::=, grantee_identified_by::=\)](#)

grant_schema_privileges::=

grantee_clause::=

grantee_identified_by::=

grant_object_privileges::=

(on_object_clause::=, grantee_clause::=)

on_object_clause::=***grant_roles_to_programs::=******program_unit::=*****Semantics*****grant_system_privileges***

Use these clauses to grant system privileges.

system_privilege

Specify the system privilege you want to grant. [Table 18-2](#) lists the system privileges, organized by the database object operated upon.

- If you grant a privilege to a **user**, then the database adds the privilege to the user's privilege domain. The user can immediately exercise the privilege. Oracle recommends that you only grant the ANY privileges to trusted users.

- If you grant a privilege to a **role**, then the database adds the privilege to the privilege domain of the role. Users who have been granted and have enabled the role can immediately exercise the privilege. Other users who have been granted the role can enable the role and exercise the privilege.

📘 See Also

[Granting a System Privilege to a User: Example](#) and ["Granting System Privileges to a Role: Example"](#)

- If you grant a privilege to **PUBLIC**, then the database adds the privilege to the privilege domains of each user. All users can immediately perform operations authorized by the privilege. Oracle recommends against granting system privileges to PUBLIC.

role

Specify the role you want to grant. You can grant a database predefined role or a user-defined role.

- If you grant a role to a **user**, then the database makes the role available to the user. The user can immediately enable the role and exercise the privileges in the privilege domain of the role.

In the case of a secure application role, you need not grant such a role directly to the user. You can let the associated PL/SQL package do this, assuming the user passes appropriate security policies. For more information, see the CREATE ROLE semantics for [USING package](#) and *Oracle AI Database Security Guide*

- If you grant a role to another **role**, then the database adds the privilege domain of the granted role to the privilege domain of the grantee role. Users who have been granted the grantee role can enable it and exercise the privileges in the granted role's privilege domain.
- If you grant a role to **PUBLIC**, then the database makes the role available to all users. All users can immediately enable the role and exercise the privileges in the privilege domain of the role.

📘 Note

Unlimited tablespace is not granted to the DBA role, but when a grant is executed to grant DBA to a user, unlimited tablespace is granted as part of the same grant, provided the user executing the GRANT command has unlimited tablespace granted with the ADMIN or GRANT ANY PRIVILEGE system privilege .

ALL PRIVILEGES

Specify ALL PRIVILEGES to grant all of the system privileges listed in [Table 18-2](#), except the SELECT ANY DICTIONARY, ALTER DATABASE LINK, and ALTER PUBLIC DATABASE LINK privileges.

However, grant and revoke ALL PRIVILEGES do not apply to ADMINISTER KEY MANAGEMENT. Granting ALL PRIVILEGES does not grant ADMINISTER KEY MANAGEMENT. Similarly, revoking ALL PRIVILEGES does not revoke ADMINISTER KEY MANAGEMENT.

① See Also

- *Oracle AI Database Security Guide* for information on the Oracle predefined roles
- "[Granting a Role to a Role: Example](#)"
- [CREATE ROLE](#) for information on creating a user-defined role

grantee_clause

Use the *grantee_clause* to specify the users or roles to which the system privilege, role, or object privilege is granted.

PUBLIC

Specify PUBLIC to grant the privileges to all users. Oracle recommends against granting system privileges to PUBLIC.

Restriction on Grantees

A user, role, or PUBLIC cannot appear more than once in the *grantee_clause*.

grantee_identified_by

The *grantee_identified_by* clause lets you assign passwords to users when granting them system privileges and roles. You must specify an equal number of users and passwords. The first password is assigned to the first user, the second password is assigned to the second user, and so on. If a specified user exists, then the database resets the user's password. If a specified user does not exist, then the database creates the user with the password.

You can set the password to a maximum length of 1024 bytes.

① See Also

[CREATE USER](#) for restrictions on usernames and passwords and "[Assigning User Passwords When Granting a System Privilege: Example](#)"

WITH ADMIN OPTION

Specify WITH ADMIN OPTION to enable the grantee to:

- Grant the privilege or role to another user or role, unless the role is a GLOBAL role
- Revoke the privilege or role from another user or role
- Alter the privilege or role to change the authorization needed to access it
- Drop the privilege or role
- Grant the role to a program unit in the grantee's schema.
- Revoke the role from a program unit in the grantee's schema.

If you grant a system privilege or role to a user without specifying WITH ADMIN OPTION, and then subsequently grant the privilege or role to the user WITH ADMIN OPTION, then the user has the ADMIN OPTION on the privilege or role.

To revoke the ADMIN OPTION on a system privilege or role from a user, you must revoke the privilege or role from the user altogether and then grant the privilege or role to the user without the ADMIN OPTION.

See Also

["Granting a Role with the ADMIN OPTION: Example"](#)

WITH DELEGATE OPTION

You can specify this clause only when granting a role to a user.

Specify WITH DELEGATE OPTION to enable the grantee to:

- Grant the role to a program unit in the grantee's schema
- Revoke the role from a program unit in the grantee's schema

If you grant a role to a user without specifying WITH DELEGATE OPTION, and then subsequently grant the role to the user WITH DELEGATE OPTION, then the user has the DELEGATE OPTION on the role.

To revoke the DELEGATE OPTION on a role from a user, you must revoke the role from the user altogether and then grant the role to the user without the DELEGATE OPTION.

See Also

- ["Granting a Role with the DELEGATE OPTION: Example"](#)
- The [grant roles to programs](#) clause for more information on granting roles to program units

Restrictions on Granting System Privileges and Roles

Privileges and roles are subject to the following restrictions:

- A privilege or role cannot appear more than once in the list of privileges and roles to be granted.
- You cannot grant a role to itself.
- You cannot grant a role IDENTIFIED GLOBALLY to anything.
- You cannot grant a role IDENTIFIED EXTERNALLY to a global user or global role.
- You cannot grant roles circularly. For example, if you grant the role banker to the role teller, then you cannot subsequently grant teller to banker.
- You cannot grant an IDENTIFIED BY role, IDENTIFIED USING role, or IDENTIFIED EXTERNALLY role to another role.

grant_schema_privileges

You can grant a schema level privilege to any user or any role if you are a user who :

- Owns the schema.
- Has a schema level privilege WITH ADMIN OPTION.

- Has the GRANT ANY SCHEMA PRIVILEGE system privilege. If you specify ALL PRIVILEGES , all the schema level privileges in [Table 18-3](#) are granted.

You cannot grant schema privileges on the SYS schema.

① See Also

Oracle AI Database Security Guide

grant_object_privileges

Use these clauses to grant object privileges.

object_privilege

Specify the object privilege you want to grant. [Table 18-4](#) lists the object privileges, organized by the type of object on which they can be granted. When you grant an object privilege on a editionable object, either to a user or to a role, the object is actualized in the edition in which the grant is made. Refer to [CREATE EDITION](#) for information on editionable object types and editions.

① Note

To grant SELECT on a view to another user, either you must own all of the objects underlying the view or you must have been granted the SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has SELECT privileges on those underlying objects.

To grant READ on a view to another user, either you must own all of the objects underlying the view or you must have been granted the READ or SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has the READ or SELECT privilege on those underlying objects.

Restriction on Object Privileges

A privilege cannot appear more than once in the list of privileges to be granted.

ALL [PRIVILEGES]

Specify ALL to grant all the privileges for the object that you have been granted with the GRANT OPTION. The user who owns the schema containing an object automatically has all privileges on the object with the GRANT OPTION. The keyword PRIVILEGES is provided for semantic clarity and is optional.

column

Specify the table or view column on which privileges are to be granted. You can specify columns only when granting the INSERT, REFERENCES, or UPDATE privilege. If you do not list columns, then the grantee has the specified privilege on all columns in the table or view.

For information on existing column object grants, query the USER_, ALL_, or DBA_COL_PRIVS data dictionary view.

① See Also

Oracle AI Database Reference for information on the data dictionary views and "[Granting Multiple Object Privileges on Individual Columns: Example](#)"

on_object_clause

The *on_object_clause* identifies the object on which the privileges are granted. Users, directory objects, editions, data mining models, Java source and resource schema objects, and SQL translation profiles are identified separately because they reside in separate namespaces.

① See Also

"[Granting Object Privileges to a Role: Example](#)"

object

Specify the schema object on which the privileges are to be granted. If you do not qualify *object* with *schema*, then the database assumes the object is in your own schema. The object can be one of the following types:

- Table, view, or materialized view
- Sequence
- Procedure, function, or package
- User-defined type
- Synonym for any of the preceding items
- Directory, library, operator, or indextype
- Java source, class, or resource

You cannot grant privileges directly to a single partition of a partitioned table.

① See Also

"[Granting Object Privileges on a Table to a User: Example](#)", "[Granting Object Privileges on a View: Example](#)", and "[Granting Object Privileges to a Sequence in Another Schema: Example](#)"

ON USER

Specify the database user you want to grant privileges to.

Restriction on Granting Privileges on Users

You cannot grant privileges on user PUBLIC.

① See Also

["Granting an Object Privilege on a User: Example"](#)

ON DIRECTORY

Specify the name of the directory object on which privileges are to be granted. You cannot qualify *directory_name* with a schema name.

① See Also

[CREATE DIRECTORY](#) and ["Granting an Object Privilege on a Directory: Example"](#)

ON EDITION

Specify the name of the edition on which the USE object privilege is to be granted. You cannot qualify *edition_name* with a schema name.

ON MINING MODEL

Specify the name of the mining model on which privileges are to be granted. If you do not qualify *mining_model_name* with *schema*, then the database assumes that the mining model is in your own schema.

ON JAVA SOURCE | RESOURCE

Specify the name of the Java source or resource schema object on which privileges are to be granted. If you do not qualify *object* with *schema*, then the database assumes that the object is in your own schema.

① See Also

[CREATE JAVA](#)

ON SQL TRANSLATION PROFILE

Specify the name of the SQL translation profile on which privileges are to be granted. If you do not qualify *profile* with *schema*, then the database assumes that the profile is in your own schema.

WITH HIERARCHY OPTION

Specify WITH HIERARCHY OPTION to grant the specified object privilege on all subobjects of *object*, such as subviews created under a view, including subobjects created subsequent to this statement.

This clause is meaningful only in combination with the READ or SELECT object privilege.

WITH GRANT OPTION

Specify WITH GRANT OPTION to enable the grantee to grant the object privileges to other users and roles.

If you grant an object privilege to a user without specifying `WITH GRANT OPTION`, and then subsequently grant the privilege to the user `WITH GRANT OPTION`, then the user has the `GRANT OPTION` on the privilege.

To revoke the `GRANT OPTION` on an object privilege from a user, you must revoke the privilege from the user altogether and then grant the privilege to the user without the `GRANT OPTION`.

Restriction on Granting `WITH GRANT OPTION`

You can specify `WITH GRANT OPTION` only when granting to a user or to `PUBLIC`, not when granting to a role.

grant_roles_to_programs

Use this clause to grant roles to program units. Such roles are called code based access control (CBAC) roles.

role

Specify the role you want to grant. You can grant a database predefined role or a user-defined role. The role must have been created by or directly granted to the schema owner of the program unit.

program_unit

Specify the program unit to which the role is to be granted. You can specify a PL/SQL function, procedure, or package. If you do not specify *schema*, then the database assumes the function, procedure, or package is in your own schema.

① See Also

Oracle AI Database Security Guide for more information on granting code based access control roles to program units

CONTAINER Clause

If the current container is a pluggable database (PDB):

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a user or role. The privilege or role is granted to the user or role only in the current PDB.

If the current container is the root:

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a common user or common role. The privilege or role is granted to the user or role only in the root.
- Specify `CONTAINER = ALL` to commonly grant a system privilege, object privilege on a common object, or role, to a common user or common role.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

Note

If you specify the **CONTAINER** clause when granting a privilege or role, then the current container must be the same container and you must specify the same **CONTAINER** clause when you revoke the privilege or role. Refer to the [CONTAINER Clause](#) of the **REVOKE** statement for more information.

Listings of System Administrative, System, Schema, and Object Privileges

Table 18-1 Administrative Privileges

Administrative Privilege Name	Operations Authorized
SYSDG	Perform the following Oracle Data Guard operations: STARTUP and SHUTDOWN. FLASHBACK DATABASE. Create, use, view, and drop restore points (including guaranteed restore points). SELECT on X\$ tables, V\$ views, and GV\$ views. Includes the ALTER DATABASE, ALTER SESSION, ALTER SYSTEM, CREATE SESSION, and SELECT ANY DICTIONARY privileges.
SYSDBA	This is the most powerful administrative privilege. It allows most operations including the ability to view user data. STARTUP and SHUTDOWN. ALTER DATABASE: open, mount, back up, or change character set. CREATE DATABASE. DROP DATABASE. ARCHIVELOG and RECOVERY. CREATE SPFILE. Includes the RESTRICTED SESSION privilege.
SYSDG	Perform the following Oracle Data Guard operations: STARTUP and SHUTDOWN. FLASHBACK DATABASE. Create, use, view, and drop restore points (including guaranteed restore points). SELECT on X\$ tables, V\$ views, and GV\$ views. Includes the ALTER DATABASE, ALTER SESSION, ALTER SYSTEM, CREATE SESSION, and SELECT ANY DICTIONARY privileges.

Table 18-1 (Cont.) Administrative Privileges

Administrative Privilege Name	Operations Authorized
SYSKM	Perform the following encryption key management operations: Connect to the database even if the database is not open. SELECT on the following views when the database is open: V\$CLIENT_SECRETS, V\$ENCRYPTED_TABLESPACES, V\$ENCRYPTION_KEYS, V\$ENCRYPTION_WALLET and V\$WALLET. Includes the ADMINISTER KEY MANAGEMENT and CREATE SESSION privileges.
SYSOPER	STARTUP and SHUTDOWN operations. ALTER DATABASE: open, mount, or back up. ARCHIVELOG and RECOVERY. CREATE SPFILE. Includes the RESTRICTED SESSION privilege.

Table 18-2 System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
Advisor Framework Privileges:	All of the advisor framework privileges are part of the DBA role.
ADVISOR	Access the advisor framework through PL/SQL packages such as DBMS_ADVISOR and DBMS_SQLTUNE.
ADMINISTER SQL TUNING SET	Create, drop, select (read), load (write), and delete SQL tuning sets owned by the grantee through the DBMS_SQLTUNE package.
ADMINISTER ANY SQL TUNING SET	Create, drop, select (read), load (write), and delete SQL tuning sets owned by any user through the DBMS_SQLTUNE package.
CREATE ANY SQL PROFILE	Accept a SQL Profile recommended by the SQL Tuning Advisor, which is accessed through Enterprise Manager or by the DBMS_SQLTUNE package. Note: This privilege has been deprecated in favor of ADMINISTER SQL MANAGEMENT OBJECT.
ALTER ANY SQL PROFILE	Alter the attributes of an existing SQL Profile. Note: This privilege has been deprecated in favor of ADMINISTER SQL MANAGEMENT OBJECT.
DROP ANY SQL PROFILE	Drop existing SQL Profiles. Note: This privilege has been deprecated in favor of ADMINISTER SQL MANAGEMENT OBJECT.
ADMINISTER SQL MANAGEMENT OBJECT	Create, alter, and drop SQL Profiles owned by any user through the DBMS_SQLTUNE package.
ANALYTIC VIEWS:	—
CREATE ANALYTIC VIEW	Create analytic views in the grantee's schema.
CREATE ANY ANALYTIC VIEW	Create analytic views in any schema except SYS, AUDSYS.
ALTER ANY ANALYTIC VIEW	Rename analytic views in any schema except SYS, AUDSYS.
DROP ANY ANALYTIC VIEW	Drop analytic views in any schema except SYS, AUDSYS.
APPLICATION IDENTITY:	—
CREATE APPLICATION IDENTITY	Create application identity.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DROP APPLICATION IDENTITY	Drop application identity.
ASSERTIONS:	—
CREATE ASSERTION	This system privilege allows the grantee to create assertions in its schema. When CREATE ASSERTION is granted, the grantee implicitly can also execute DROP ASSERTION and ALTER ASSERTION on assertions in its schema.
CREATE ANY ASSERTION	This system privilege allows the grantee to create assertions in any schema except SYS, AUDSYS.
ALTER ANY ASSERTION	This system privilege allows the grantee to alter assertions in any schema except SYS, AUDSYS.
DROP ANY ASSERTION	This system privilege allows the grantee to drop assertions in any schema except SYS, AUDSYS.
ATTRIBUTE DIMENSIONS:	—
CREATE ATTRIBUTE DIMENSION	Create attribute dimensions in the grantee's schema.
CREATE ANY ATTRIBUTE DIMENSION	Create attribute dimensions in any schema except SYS, AUDSYS.
ALTER ANY ATTRIBUTE DIMENSION	Rename attribute dimensions in any schema except SYS, AUDSYS.
DROP ANY ATTRIBUTE DIMENSION	Drop attribute dimensions in any schema except SYS, AUDSYS.
AUDIT:	—
AUDIT ANY	Audit an object in any schema, except SYS, AUDSYS, using AUDIT <i>schema_objects</i> statements.
AUDIT SYSTEM	Issue AUDIT statements.
ADMINISTER FINE GRAINED AUDIT POLICY	Allow management of fine-grained audit policies
CLUSTERS:	—
CREATE CLUSTER	Create clusters in the grantee's schema.
CREATE ANY CLUSTER	Create clusters in any schema except SYS, AUDSYS. Behaves similarly to CREATE ANY TABLE.
ALTER ANY CLUSTER	Alter clusters in any schema except SYS, AUDSYS.
DROP ANY CLUSTER	Drop clusters in any schema except SYS, AUDSYS.
CONTEXTS:	—
CREATE ANY CONTEXT	Create any context namespace.
DROP ANY CONTEXT	Drop any context namespace.
DATA GRANT:	—
CREATE DATA GRANT	Create data grants for rows and columns on tables and views in any schema.
ADMINISTER ANY DATA GRANT	Create data grants for rows and columns on tables and views.
SET USE DATA GRANTS ONLY	Enable mandatory access control for a table or view using SET USE DATA GRANTS ONLY statement.
DROP ANY DATA GRANT	Drop data grants for rows and columns on tables and views in any schema.
DATA REDACTION:	—

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
EXEMPT REDACTION POLICY	Bypass any existing Oracle Data Redaction policies and view actual data from tables or views on which Data Redaction policies are defined.
ADMINISTER REDACTION POLICY	Allow management of Redaction policies .
DATA ROLE:	—
CREATE DATA ROLE	Create data role.
DROP DATA ROLE	Drop data role.
GRANT ANY DATA ROLE	Granting and revoking data roles.
DATABASE:	—
ALTER DATABASE	Alter the database.
ALTER SYSTEM	Issue ALTER SYSTEM statements.
DATABASE LINKS:	—
CREATE DATABASE LINK	Create private database links in the grantee's schema.
CREATE PUBLIC DATABASE LINK	Create public database links.
ALTER DATABASE LINK	Modify a fixed-user database link when the password of the connection or authentication user changes.
ALTER PUBLIC DATABASE LINK	Modify a public fixed-user database link when the password of the connection or authentication user changes.
DROP PUBLIC DATABASE LINK	Drop public database links.
DEBUGGING:	—
DEBUG CONNECT SESSION	Connect the current session to a debugger.
DEBUG ANY PROCEDURE	Debug all PL/SQL and Java code in any database object. Display information on all SQL statements executed by the application. Note: Granting this privilege is equivalent to granting the DEBUG object privilege on all applicable objects in the database.
DICTIONARIES:	—
ANALYZE ANY DICTIONARY	Analyze any data dictionary object.
DIMENSIONS:	—
CREATE DIMENSION	Create dimensions in the grantee's schema.
CREATE ANY DIMENSION	Create dimensions in any schema except SYS, AUDSYS.
ALTER ANY DIMENSION	Alter dimensions in any schema except SYS, AUDSYS.
DROP ANY DIMENSION	Drop dimensions in any schema except SYS, AUDSYS.
DIRECTIVES:	—
CREATE ANY VALIDATION DIRECTIVE	Create a directive in your own schema on a table in another user's schema . Create a directive in an other schema on a table in another user's schema . This privilege grants read-equivalent access to all duality view DML payloads.
DIRECTORIES:	—
CREATE ANY DIRECTORY	Create directory database objects.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DROP ANY DIRECTORY	Drop directory database objects.
DOMAINS:	—
CREATE DOMAIN	Create a domain in your own schema.
CREATE ANY DOMAIN	Create a domain in any schema.
ALTER ANY DOMAIN	Alter a domain in any schema.
DROP ANY DOMAIN	Drop a domain in any schema.
EXECUTE ANY DOMAIN	Refer to a domain in any schema.
EDITIONS:	—
CREATE ANY EDITION	Create editions.
DROP ANY EDITION	Drop editions.
END USER:	—
CREATE END USER	Create end users.
ALTER END USER	Alter end users.
DROP END USER	Drop end users.
END USER CONTEXT:	—
CREATE END USER CONTEXT	Create end user context.
DROP END USER CONTEXT	Drop end user context.
UPDATE ANY END USER CONTEXT	Modify end user context.
SELECT ANY END USER CONTEXT	Retrieve attributes and values for a context using the ORA_END_USER_CONTEXT function.
FLASHBACK DATA ARCHIVES:	—
FLASHBACK ARCHIVE ADMINISTER	Create, alter, or drop any flashback data archive.
HIERARCHIES	—
CREATE HIERARCHY	Create hierarchies in the grantee's schema.
CREATE ANY HIERARCHY	Create hierarchies in any schema except SYS, AUDSYS.
ALTER ANY HIERARCHY	Rename hierarchies in any schema except SYS, AUDSYS.
DROP ANY HIERARCHY	Drop hierarchies in any schema except SYS, AUDSYS.
INDEXES:	—
CREATE ANY INDEX	Create in any schema, except SYS, AUDSYS, a domain index or an index on any table in any schema except SYS, AUDSYS.
ALTER ANY INDEX	Alter indexes in any schema except SYS, AUDSYS.
DROP ANY INDEX	Drop indexes in any schema except SYS, AUDSYS.
INDEXTYPES:	—
CREATE INDEXTYPE	Create indextypes in the grantee's schema.
CREATE ANY INDEXTYPE	Create indextypes in any schema except SYS and create comments on indextypes in any schema except SYS.
ALTER ANY INDEXTYPE	Modify indextypes in any schema except SYS, AUDSYS.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DROP ANY INDEXTYPE	Drop indextypes in any schema except SYS, AUDSYS.
EXECUTE ANY INDEXTYPE	Reference indextypes in any schema except SYS, AUDSYS.
JOB SCHEDULER OBJECTS:	The following privileges are needed to execute procedures in the DBMS_SCHEDULER package. This privileges do not apply to lightweight jobs, which are not database objects. Refer to <i>Oracle AI Database Administrator's Guide</i> for more information about lightweight jobs.
CREATE JOB	Create, alter, or drop jobs, chains, schedules, programs, credentials, resource objects, or incompatibility resource objects in the grantee's schema.
CREATE ANY JOB	Create, alter, or drop jobs, chains, schedules, programs, credentials, resource objects, or incompatibility resource objects in any schema except SYS, AUDSYS. Note: This extremely powerful privilege allows the grantee to execute code as any other user. It should be granted with caution.
CREATE EXTERNAL JOB	Create in the grantee's schema an executable scheduler job that runs on the operating system.
EXECUTE ANY CLASS	Specify any job class in a job in the grantee's schema.
EXECUTE ANY PROGRAM	Use any program in a job in the grantee's schema.
MANAGE SCHEDULER	Create, alter, or drop any job class, window, or window group.
USE ANY JOB RESOURCE	Associate any schedule resource object with any program or job in the grantee's schema.
KEY MANAGEMENT FRAMEWORK:	—
ADMINISTER KEY MANAGEMENT	Manage keys and keystores.
LIBRARIES:	Caution: CREATE LIBRARY, CREATE ANY LIBRARY, ALTER ANY LIBRARY, and EXECUTE ANY LIBRARY are extremely powerful privileges that should be granted only to trusted users. Refer to <i>Oracle AI Database Security Guide</i> before granting these privileges.
CREATE LIBRARY	Create external procedure or function libraries in the grantee's schema.
CREATE ANY LIBRARY	Create external procedure or function libraries in any schema except SYS, AUDSYS.
ALTER ANY LIBRARY	Alter external procedure or function libraries in any schema except SYS, AUDSYS.
DROP ANY LIBRARY	Drop external procedure or function libraries in any schema except SYS, AUDSYS.
EXECUTE ANY LIBRARY	Use external procedure or function libraries in any schema except SYS, AUDSYS.
LOGMINER:	—
LOGMINING	Execute procedures in the DBMS_LOGMNR package in a CDB or a PDB. Query the contents of the V\$LOGMNR_CONTENTS view.
MATERIALIZED VIEWS:	—
CREATE MATERIALIZED VIEW	Create materialized views in the grantee's schema.
CREATE ANY MATERIALIZED VIEW	Create materialized views in any schema except SYS, AUDSYS.
ALTER ANY MATERIALIZED VIEW	Alter materialized views in any schema except SYS, AUDSYS.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DROP ANY MATERIALIZED VIEW	Drop materialized views in any schema except SYS, AUDSYS.
QUERY REWRITE	This privilege has been deprecated. No privileges are needed for a user to enable rewrite for a materialized view that references tables or views in the user's own schema.
GLOBAL QUERY REWRITE	Enable rewrite using a materialized view when that materialized view references tables or views in any schema except SYS.
ON COMMIT REFRESH	Create a refresh-on-commit materialized view on any table in the database. Alter a refresh-on-demand materialized view on any table in the database to refresh-on-commit.
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.
MINING MODELS:	—
CREATE MINING MODEL	Create mining models in the grantee's schema using the DBMS_DATA_MINING.CREATE_MODEL procedure.
CREATE ANY MINING MODEL	Create mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.CREATE_MODEL procedure.
ALTER ANY MINING MODEL	Change the mining model name or the associated cost matrix of a model in any schema, except SYS, AUDSYS, using the applicable DBMS_DATA_MINING procedures.
DROP ANY MINING MODEL	Drop mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.DROP_MODEL procedure.
SELECT ANY MINING MODEL	Score or view mining models in any schema except SYS, AUDSYS. Scoring is done either with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures.
COMMENT ANY MINING MODEL	Create comments on mining models in any schema, except SYS, AUDSYS, using the SQL COMMENT statement.
OLAP CUBES:	The following privileges are valid when you are using the database with the OLAP option.
CREATE CUBE	Create OLAP cubes in the grantee's schema.
CREATE ANY CUBE	Create OLAP cubes in any schema except SYS, AUDSYS.
ALTER ANY CUBE	Alter OLAP cubes in any schema except SYS, AUDSYS.
DROP ANY CUBE	Drop OLAP cubes in any schema except SYS, AUDSYS.
SELECT ANY CUBE	Query or view OLAP cubes in any schema except SYS, AUDSYS.
UPDATE ANY CUBE	Update OLAP cubes in any schema except SYS, AUDSYS.
OLAP CUBE MEASURE FOLDERS:	The following privileges are valid when you are using the database with the OLAP option.
CREATE MEASURE FOLDER	Create OLAP measure folders in the grantee's schema.
CREATE ANY MEASURE FOLDER	Create OLAP measure folders in any schema except SYS, AUDSYS.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DELETE ANY MEASURE FOLDER	Delete a measure from an OLAP measure folder in any schema except SYS, AUDSYS.
DROP ANY MEASURE FOLDER	Drop OLAP measure folders in any schema except SYS, AUDSYS.
INSERT ANY MEASURE FOLDER	Insert a measure into an OLAP measure folder in any schema except SYS, AUDSYS.
OLAP CUBE DIMENSIONS:	The following privileges are valid when you are using the database with the OLAP option.
CREATE CUBE DIMENSION	Create OLAP cube dimension in the grantee's schema.
CREATE ANY CUBE DIMENSION	Create OLAP cube dimensions in any schema except SYS, AUDSYS.
ALTER ANY CUBE DIMENSION	Alter OLAP cube dimensions in any schema except SYS, AUDSYS.
DELETE ANY CUBE DIMENSION	Delete from OLAP cube dimensions in any schema except SYS, AUDSYS.
DROP ANY CUBE DIMENSION	Drop OLAP cube dimensions in any schema except SYS, AUDSYS.
INSERT ANY CUBE DIMENSION	Insert into OLAP cube dimensions in any schema except SYS, AUDSYS.
SELECT ANY CUBE DIMENSION	View or query OLAP cube dimensions in any schema except SYS, AUDSYS.
UPDATE ANY CUBE DIMENSION	Update OLAP cube dimensions in any schema except SYS, AUDSYS.
OLAP CUBE BUILD PROCESSES:	—
CREATE CUBE BUILD PROCESS	Create OLAP cube build processes in the grantee's schema.
CREATE ANY CUBE BUILD PROCESS	Create OLAP cube build processes in any schema except SYS, AUDSYS.
DROP ANY CUBE BUILD PROCESS	Drop OLAP cube build processes in any schema except SYS, AUDSYS.
UPDATE ANY CUBE BUILD PROCESS	Update OLAP cube build processes in any schema except SYS, AUDSYS.
OPERATORS:	—
CREATE OPERATOR	Create an operator and its bindings in the grantee's schema.
CREATE ANY OPERATOR	Create an operator and its bindings in any schema and create a comment on an operator in any schema.
ALTER ANY OPERATOR	Modify operators in any schema.
DROP ANY OPERATOR	Drop operators in any schema.
EXECUTE ANY OPERATOR	Reference operators in any schema.
OUTLINES:	—
CREATE ANY OUTLINE	Create public outlines that can be used in any schema that uses outlines.
ALTER ANY OUTLINE	Modify outlines.
DROP ANY OUTLINE	Drop outlines.
PDB LOCKDOWN PROFILES:	—
CREATE LOCKDOWN PROFILE	Create PDB lockdown profiles.
ALTER LOCKDOWN PROFILE	Alter PDB lockdown profiles.
DROP LOCKDOWN PROFILE	Drop PDB lockdown profiles.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
PLAN MANAGEMENT:	—
ADMINISTER SQL MANAGEMENT OBJECT	Perform controlled manipulation of plan history and SQL plan baselines maintained for various SQL statements.
PLUGGABLE DATABASES:	—
CREATE PLUGGABLE DATABASE	Create a PDB. Plug in a PDB that was previously unplugged from a CDB. Clone a PDB.
SET CONTAINER	Allow a common user to switch into the container for which this privilege was granted. This privilege can be granted only to a common user or common role.
PROCEDURES:	—
CREATE PROCEDURE	Create stored procedures, functions, or packages in the grantee's schema.
CREATE ANY PROCEDURE	Create stored procedures, functions, or packages in any schema except SYS, AUDSYS.
ALTER ANY PROCEDURE	Alter stored procedures, functions, or packages in any schema except SYS, AUDSYS.
DROP ANY PROCEDURE	Drop stored procedures, functions, or packages in any schema except SYS, AUDSYS.
EXECUTE ANY PROCEDURE	Execute procedures or functions, either standalone or packaged. Reference public package variables in any schema except SYS, AUDSYS.
INHERIT ANY REMOTE PRIVILEGES	Execute definer's rights procedures or functions that contain current user database links.
PROFILES:	—
CREATE PROFILE	Create profiles.
ALTER PROFILE	Alter profiles.
DROP PROFILE	Drop profiles.
PROPERTY GRAPHS:	—
CREATE PROPERTY GRAPH	Create property graph in the grantee's schema.
CREATE ANY PROPERTY GRAPH	Create property graph in any schema except SYS, AUDSYS.
ALTER ANY PROPERTY GRAPH	Alter property graph in any schema except SYS, AUDSYS.
DROP ANY PROPERTY GRAPH	Drop property graph in any schema except SYS, AUDSYS.
READ ANY PROPERTY GRAPH	Query property graph in any schema except SYS, AUDSYS.
COMMENT ANY PROPERTY GRAPH	Create comments on property graphs in any schema except SYS, AUDSYS.
ROLES:	—
CREATE ROLE	Create roles.
ALTER ANY ROLE	Alter any role in the database.
DROP ANY ROLE	Drop roles.
GRANT ANY ROLE	Grant any role in the database.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
ROLLBACK SEGMENTS:	—
CREATE ROLLBACK SEGMENT	Create rollback segments.
ALTER ROLLBACK SEGMENT	Alter rollback segments.
DROP ROLLBACK SEGMENT	Drop rollback segments.
SEQUENCES:	—
CREATE SEQUENCE	Create sequences in the grantee's schema.
CREATE ANY SEQUENCE	Create sequences in any schema except SYS, AUDSYS.
ALTER ANY SEQUENCE	Alter sequences in any schema except SYS, AUDSYS.
DROP ANY SEQUENCE	Drop sequences in any schema except SYS, AUDSYS.
SELECT ANY SEQUENCE	Reference sequences in any schema except SYS, AUDSYS.
SESSIONS:	—
CREATE SESSION	Connect to the database.
ALTER RESOURCE COST	Set costs for session resources.
ALTER SESSION	Enable and disable the SQL trace facility.
RESTRICTED SESSION	Logon after the instance is started using the SQL*Plus STARTUP RESTRICT statement.
SNAPSHOTS:	See MATERIALIZED VIEWS
SQL Firewall Administration	—
ADMINISTER SQL FIREWALL	This system privilege is required to execute the PL/SQL procedures in SYS.DBMS_SQL_FIREWALL package. Just like any other system privileges, SYS is assumed to have this privilege. However this system privilege will not be granted to the DBA role by default.
SQL TRANSLATION PROFILES:	—
CREATE SQL TRANSLATION PROFILE	Create SQL translation profiles in the grantee's schema.
CREATE ANY SQL TRANSLATION PROFILE	Create SQL translation profiles in any schema except SYS, AUDSYS.
ALTER ANY SQL TRANSLATION PROFILE	Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile in any schema except SYS, AUDSYS.
USE ANY SQL TRANSLATION PROFILE	Use SQL translation profiles in any schema except SYS, AUDSYS.
DROP ANY SQL TRANSLATION PROFILE	Drop SQL translation profiles in any schema except SYS, AUDSYS.
TRANSLATE ANY SQL	Translate SQL through the grantee's SQL translation profile for any user.
SYNONYMS:	Caution: CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM are extremely powerful privileges that should be granted only to trusted users. Refer to <i>Oracle AI Database Security Guide</i> before granting these privileges.
CREATE SYNONYM	Create synonyms in the grantee's schema.
CREATE ANY SYNONYM	Create private synonyms in any schema except SYS, AUDSYS.
CREATE PUBLIC SYNONYM	Create public synonyms.
DROP ANY SYNONYM	Drop private synonyms in any schema except SYS, AUDSYS.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
DROP PUBLIC SYNONYM	Drop public synonyms.
TABLES:	Note: For external tables, the only valid privileges are CREATE ANY TABLE, ALTER ANY TABLE, DROP ANY TABLE, READ ANY TABLE, and SELECT ANY TABLE.
CREATE TABLE	Create tables in the grantee's schema.
CREATE ANY TABLE	Create a table in any schema except SYS, AUDSYS. The owner of the schema containing the table must have space quota on the tablespace to contain the table.
ALTER ANY TABLE	Alter a table or view in any schema except SYS, AUDSYS.
BACKUP ANY TABLE	Use the Export utility to incrementally export objects from the schema of other users except SYS, AUDSYS.
DELETE ANY TABLE	Delete rows from tables, table partitions, or views in any schema except SYS, AUDSYS.
DROP ANY TABLE	Drop or truncate tables or table partitions in any schema except SYS, AUDSYS.
INSERT ANY TABLE	Insert rows into tables and views in any schema except SYS, AUDSYS.
LOCK ANY TABLE	Lock tables and views in any schema except SYS, AUDSYS.
READ ANY TABLE	Query tables, views, or materialized views in any schema except SYS, AUDSYS.
SELECT ANY TABLE	Query tables, views, or materialized views in any schema except SYS, AUDSYS. Obtain row locks using a SELECT ... FOR UPDATE.
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.
UPDATE ANY TABLE	Update rows in tables and views in any schema except SYS, AUDSYS.
REDEFINE ANY TABLE	Perform online redefinition without granting any of the privileges in USER or FULL mode.
TABLE RETENTION	Create a blockchain table or an immutable table whose table retention exceeds the threshold specified by the parameter BLOCKCHAIN_TABLE_RETENTION_THRESHOLD. Increase the table retention for an existing blockchain table or immutable table to a value above the threshold specified by the parameter BLOCKCHAIN_TABLE_RETENTION_THRESHOLD.
TABLESPACES:	—
CREATE TABLESPACE	Create tablespaces.
ALTER TABLESPACE	Alter tablespaces.
DROP TABLESPACE	Drop tablespaces.
MANAGE TABLESPACE	Take tablespaces offline and online and begin and end tablespace backups.
UNLIMITED TABLESPACE	Use an unlimited amount of any tablespace. This privilege overrides any specific quotas assigned. If you revoke this privilege from a user, then the user's schema objects remain but further tablespace allocation is denied unless authorized by specific tablespace quotas. You cannot grant this system privilege to roles.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
TRIGGERS:	—
CREATE TRIGGER	Create database triggers in the grantee's schema.
CREATE ANY TRIGGER	Create database triggers in any schema except SYS, AUDSYS.
ALTER ANY TRIGGER	Enable, disable, or compile database triggers in any schema except SYS, AUDSYS.
DROP ANY TRIGGER	Drop database triggers in any schema except SYS, AUDSYS.
ADMINISTER DATABASE TRIGGER	Create a trigger on DATABASE. You must also have the CREATE TRIGGER or CREATE ANY TRIGGER system privilege.
TYPES:	—
CREATE TYPE	Create object types and object type bodies in the grantee's schema.
CREATE ANY TYPE	Create object types and object type bodies in any schema except SYS, AUDSYS.
ALTER ANY TYPE	Alter object types in any schema except SYS, AUDSYS.
DROP ANY TYPE	Drop object types and object type bodies in any schema except SYS, AUDSYS.
EXECUTE ANY TYPE	Use and reference object types and collection types in any schema except SYS, AUDSYS, and invoke methods of an object type in any schema, except SYS, AUDSYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema.
UNDER ANY TYPE	Create subtypes under any nonfinal object types.
USERS:	—
CREATE USER	Create users. This privilege also allows the creator to: • Assign quotas on any tablespace. • Set default and temporary tablespaces. • Assign a profile as part of a CREATE USER statement.
ALTER USER	Alter any user except SYS. This privilege authorizes the grantee to: • Change another user's password or authentication method. • Assign quotas on any tablespace. • Set default and temporary tablespaces. • Assign a profile and default roles.
DROP USER	Drop users
VIEWS:	—
CREATE VIEW	Create views in the grantee's schema.
CREATE ANY VIEW	Create views in any schema except SYS, AUDSYS.
DROP ANY VIEW	Drop views in any schema except SYS, AUDSYS.
UNDER ANY VIEW	Create subviews under any object views.
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
MERGE ANY VIEW	If a user has been granted the MERGE ANY VIEW privilege, then for any query issued by that user, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator. See <i>Oracle AI Database SQL Tuning Guide</i> for information on view merging.
VIRTUAL PRIVATE DATABASE	
EXEMPT ACCESS POLICY	Bypass fine-grained access control. Caution: This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.
ADMINISTER ROW LEVEL SECURITY POLICY	Allow management of Virtual Private Database (VPD) policies (fine-grained access control, row-level security)
MISCELLANEOUS:	
ANALYZE ANY	Analyze a table, cluster, or index in any schema except SYS.
BECOME USER	Allow users of the Data Pump Import utility (impdp) and the original Import utility (imp) to assume the identity of another user in order to perform operations that cannot be directly performed by a third party (for example, loading objects such as object privilege grants). Allow Streams administrators to create or alter capture users and apply users in a Streams environment. By default this privilege is part of the DBA role. Database Vault removes this privileges from the DBA role. Therefore, this privilege is needed by Streams only in an environment where Database Vault is installed.
CHANGE NOTIFICATION	Create a registration on queries and receive database change notifications in response to DML or DDL changes to the objects associated with the registered queries. Refer to <i>Oracle AI Database Development Guide</i> for more information on database change notification.
COMMENT ANY TABLE	Comment on a table, view, or column in any schema except SYS, AUDSYS.
ENABLE DIAGNOSTICS	- Set debug-events via ALTER SESSION or ALTER SYSTEM - Set debug-actions to execute during an event via ALTER SESSION or ALTER SYSTEM - Execute debug-actions immediately via ALTER SESSION or ALTER SYSTEM by specifying the IMMEDIATE keyword instead of an event name - Set the event parameter in the spfile via ALTER SYSTEM
FORCE ANY TRANSACTION	Force the commit or rollback of any in-doubt distributed transaction in the local database. Induce the failure of a distributed transaction.
FORCE TRANSACTION	Force the commit or rollback of the grantee's in-doubt distributed transactions in the local database.
GRANT ANY OBJECT PRIVILEGE	Grant any object privilege that the object owner is permitted to grant. Revoke any object privilege that was granted by the object owner or by some other user with the GRANT ANY OBJECT PRIVILEGE privilege.
GRANT ANY PRIVILEGE	Grant any system privilege.

Table 18-2 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

System Privilege Name	Operations Authorized
INHERIT ANY PRIVILEGES	Execute invoker's rights procedures owned by the grantee with the privileges of the invoker.
KEEP DATE TIME	The SYSDATE and SYSTIMESTAMP functions return their original values during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. Note: If this privilege is granted or revoked between runtime and failover of a request, then the original values are not returned during replay for Application Continuity for that request.
KEEP SYSGUID	The SYS_GUID function returns its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. Note: If this privilege is granted or revoked between runtime and failover of a request, then the original value is not returned during replay for Application Continuity for that request.
PURGE DBA_RECYCLEBIN	Remove all objects from the system-wide recycle bin.
RESUMABLE	Enable resumable space allocation.
SELECT ANY DICTIONARY	Query any data dictionary object in the dictionary protected schema, with the exception of the following objects: SYS.DEFAULT_PWD\$, SYS.ENC\$, SYS.LINK\$, SYS.USER\$, SYS.USER_HISTORY\$, and SYS.X\$VERIFIERS. Note: The privilege will NOT allow the grantee to execute SELECT . . . FOR UPDATE on a dictionary table. It will allow "READ" on dictionary objects
SELECT ANY TRANSACTION	Query the contents of the FLASHBACK_TRANSACTION_QUERY view. Caution: This is a very powerful system privilege, as it lets the grantee view all data in the database, including past data. This privilege should be granted only to users who need to use the Oracle Flashback Transaction Query feature.

Table 18-3 Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
ANALYTIC VIEWS	—
CREATE ANY ANALYTIC VIEW	Create analytic views in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE ANALYTIC VIEW privilege.
ALTER ANY ANALYTIC VIEW	Rename analytic views in any schema except SYS, AUDSYS.
DROP ANY ANALYTIC VIEW	Drop analytic views in any schema except SYS, AUDSYS .
ASSERTIONS	—
CREATE ANY ASSERTION	This system privilege allows the grantee to create assertions in any schema except SYS, AUDSYS.
ALTER ANY ASSERTION	This system privilege allows the grantee to alter assertions in any schema except SYS, AUDSYS.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
DROP ANY ASSERTION	This system privilege allows the grantee to drop assertions in any schema except SYS, AUDSYS.
ATTRIBUTE DIMENSIONS	—
CREATE ANY ATTRIBUTE DIMENSION	Create attribute dimensions in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE ATTRIBUTE DIMENSION privilege.
ALTER ANY ATTRIBUTE DIMENSION	Rename attribute dimensions in any schema except SYS, AUDSYS.
DROP ANY ATTRIBUTE DIMENSION	Drop attribute dimensions in any schema except SYS, AUDSYS.
AUDIT GROUP:	—
AUDIT ANY	Audit an object in any schema, except SYS, AUDSYS, using AUDIT <i>schema_objects</i> statements.
ADMINISTER FINE GRAINED AUDIT POLICY	Allow management of fine-grained audit policies in a schema.
CLUSTERS:	—
CREATE ANY CLUSTER	Create clusters in any schema except SYS, AUDSYS. Behaves similarly to CREATE ANY TABLE. If the grantee is the schema owner, then grantee should have been granted CREATE CLUSTER privilege.
ALTER ANY CLUSTER	Alter clusters in any schema except SYS, AUDSYS.
DROP ANY CLUSTER	Drop clusters in any schema except SYS, AUDSYS.
DATA REDACTION:	—
EXEMPT REDACTION POLICY	Bypass any existing Oracle Data Redaction policies and view actual data from tables or views on which Data Redaction policies are defined in the schema.
ADMINISTER REDACTION POLICY	Allow management of redaction policies in a schema.
DIMENSIONS:	—
CREATE ANY DIMENSION	Create dimensions in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE DIMENSION privilege.
ALTER ANY DIMENSION	Alter dimensions in any schema except SYS, AUDSYS.
DROP ANY DIMENSION	Drop dimensions in any schema except SYS, AUDSYS.
DOMAINS:	—
CREATE ANY DOMAIN	Create a DOMAIN in any non-dictionary protected schema. If the grantee is the schema owner, then grantee should have been granted CREATE DOMAIN privilege.
ALTER ANY DOMAIN	Rename a domain in any non-dictionary protected schema.
DROP ANY DOMAIN	Drop a domain in any non-dictionary protected schema.
EXECUTE ANY DOMAIN	Execute a domain in a designated non-dictionary protected schema.
HIERARCHIES	—
CREATE ANY HIERARCHY	Create hierarchies in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE HIERARCHY privilege.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
ALTER ANY HIERARCHY	Rename hierarchies in any schema except SYS, AUDSYS.
DROP ANY HIERARCHY	Drop hierarchies in any schema except SYS, AUDSYS.
INDEXES:	—
CREATE ANY INDEX	Create in any schema, except SYS, AUDSYS, a domain index or an index on any table in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE INDEX privilege.
ALTER ANY INDEX	Alter indexes in any schema except SYS, AUDSYS.
DROP ANY INDEX	Drop indexes in any schema except SYS, AUDSYS.
INDEXTYPES:	—
CREATE ANY INDEXTYPE	Create indextypes in any schema except SYS and create comments on indextypes in any schema except SYS. If the grantee is the schema owner, then grantee should have been granted CREATE INDEXTYPE privilege.
ALTER ANY INDEXTYPE	Modify indextypes in any schema except SYS, AUDSYS.
DROP ANY INDEXTYPE	Drop indextypes in any schema except SYS, AUDSYS.
EXECUTE ANY INDEXTYPE	Reference indextypes in any schema except SYS, AUDSYS.
JOB SCHEDULER OBJECTS:	The following privileges are needed to execute procedures in the DBMS_SCHEDULER package. This privileges do not apply to lightweight jobs, which are not database objects. Refer to <i>Oracle AI Database Administrator's Guide</i> for more information about lightweight jobs.
CREATE ANY JOB	Create, alter, or drop jobs, chains, schedules, programs, credentials, resource objects, or incompatibility resource objects in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE JOB privilege. Note: This extremely powerful privilege allows the grantee to execute code as any other user. It should be granted with caution.
LIBRARIES:	Caution: CREATE LIBRARY, CREATE ANY LIBRARY, ALTER ANY LIBRARY, and EXECUTE ANY LIBRARY are extremely powerful privileges that should be granted only to trusted users. Refer to <i>Oracle AI Database Security Guide</i> before granting these privileges.
CREATE ANY LIBRARY	Create external procedure or function libraries in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE LIBRARY privilege.
ALTER ANY LIBRARY	Alter external procedure or function libraries in any schema except SYS, AUDSYS.
DROP ANY LIBRARY	Drop external procedure or function libraries in any schema except SYS, AUDSYS.
EXECUTE ANY LIBRARY	Use external procedure or function libraries in any schema except SYS, AUDSYS.
MATERIALIZED VIEWS:	—

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
CREATE ANY MATERIALIZED VIEW	Create materialized views in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE MATERIALIZED VIEW privilege.
ALTER ANY MATERIALIZED VIEW	Alter materialized views in any schema except SYS, AUDSYS.
DROP ANY MATERIALIZED VIEW	Drop materialized views in any schema except SYS, AUDSYS.
GLOBAL QUERY REWRITE	Enable rewrite using a materialized view when that materialized view references tables or views in any schema except SYS.
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.
MINING MODELS:	—
CREATE ANY MINING MODEL	Create mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.CREATE_MODEL procedure. If the grantee is the schema owner, then grantee should have been granted CREATE MINING MODEL privilege.
ALTER ANY MINING MODEL	Change the mining model name or the associated cost matrix of a model in any schema, except SYS, AUDSYS, using the applicable DBMS_DATA_MINING procedures.
DROP ANY MINING MODEL	Drop mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.DROP_MODEL procedure.
SELECT ANY MINING MODEL	Score or view mining models in any schema except SYS, AUDSYS. Scoring is done either with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures.
COMMENT ANY MINING MODEL	Create comments on mining models in any schema, except SYS, AUDSYS, using the SQL COMMENT statement.
OLAP CUBES:	The following privileges are valid when you are using the database with the OLAP option.
CREATE ANY CUBE	Create OLAP cubes in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE CUBE privilege.
ALTER ANY CUBE	Alter OLAP cubes in any schema except SYS, AUDSYS.
DROP ANY CUBE	Drop OLAP cubes in any schema except SYS, AUDSYS.
SELECT ANY CUBE	Query or view OLAP cubes in any schema except SYS, AUDSYS.
UPDATE ANY CUBE	Update OLAP cubes in any schema except SYS, AUDSYS.
OLAP CUBE MEASURE FOLDERS:	The following privileges are valid when you are using the database with the OLAP option.
CREATE ANY MEASURE FOLDER	Create OLAP measure folders in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE MEASURE FOLDER privilege.
DELETE ANY MEASURE FOLDER	Delete a measure from an OLAP measure folder in any schema except SYS, AUDSYS.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
DROP ANY MEASURE FOLDER	Drop OLAP measure folders in any schema except SYS, AUDSYS.
INSERT ANY MEASURE FOLDER	Insert a measure into an OLAP measure folder in any schema except SYS, AUDSYS.
OLAP CUBE DIMENSIONS:	The following privileges are valid when you are using the database with the OLAP option.
CREATE ANY CUBE DIMENSION	Create OLAP cube dimensions in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE CUBE DIMENSION privilege.
ALTER ANY CUBE DIMENSION	Alter OLAP cube dimensions in any schema except SYS, AUDSYS.
DELETE ANY CUBE DIMENSION	Delete from OLAP cube dimensions in any schema except SYS, AUDSYS.
DROP ANY CUBE DIMENSION	Drop OLAP cube dimensions in any schema except SYS, AUDSYS.
INSERT ANY CUBE DIMENSION	Insert into OLAP cube dimensions in any schema except SYS, AUDSYS.
SELECT ANY CUBE DIMENSION	View or query OLAP cube dimensions in any schema except SYS, AUDSYS.
UPDATE ANY CUBE DIMENSION	Update OLAP cube dimensions in any schema except SYS, AUDSYS.
OLAP CUBE BUILD PROCESSES:	—
CREATE ANY CUBE BUILD PROCESS	Create OLAP cube build processes in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE CUBE BUILD PROCESS privilege.
DROP ANY CUBE BUILD PROCESS	Drop OLAP cube build processes in any schema except SYS, AUDSYS.
UPDATE ANY CUBE BUILD PROCESS	Update OLAP cube build processes in any schema except SYS, AUDSYS.
OPERATORS:	—
CREATE ANY OPERATOR	Create an operator and its bindings in any schema and create a comment on an operator in any schema. If the grantee is the schema owner, then grantee should have been granted CREATE OPERATOR privilege.
ALTER ANY OPERATOR	Modify operators in any schema.
DROP ANY OPERATOR	Drop operators in any schema.
EXECUTE ANY OPERATOR	Reference operators in any schema.
PROCEDURES:	—
CREATE ANY PROCEDURE	Create stored procedures, functions, or packages in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE PROCEDURE privilege.
ALTER ANY PROCEDURE	Alter stored procedures, functions, or packages in any schema except SYS, AUDSYS.
DROP ANY PROCEDURE	Drop stored procedures, functions, or packages in any schema except SYS, AUDSYS.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
EXECUTE ANY PROCEDURE	Execute procedures or functions, either standalone or packaged. Reference public package variables in any schema except SYS, AUDSYS.
PROPERTY GRAPHS:	—
CREATE ANY PROPERTY GRAPH	Create property graph in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE PROPERTY GRAPH privilege.
ALTER ANY PROPERTY GRAPH	Alter property graph in any schema except SYS, AUDSYS.
DROP ANY PROPERTY GRAPH	Drop property graph in any schema except SYS, AUDSYS.
READ ANY PROPERTY GRAPH	Query property graph in any schema except SYS, AUDSYS.
COMMENT ANY PROPERTY GRAPH	Create comments on property graphs in any schema except SYS, AUDSYS.
SEQUENCES:	—
CREATE ANY SEQUENCE	Create sequences in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE SEQUENCE privilege.
ALTER ANY SEQUENCE	Alter sequences in any schema except SYS, AUDSYS.
DROP ANY SEQUENCE	Drop sequences in any schema except SYS, AUDSYS.
SELECT ANY SEQUENCE	Reference sequences in any schema except SYS, AUDSYS.
SQL TRANSLATION PROFILES:	—
CREATE ANY SQL TRANSLATION PROFILE	Create SQL translation profiles in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE SQL TRANSLATION PROFILE privilege.
ALTER ANY SQL TRANSLATION PROFILE	Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile in any schema except SYS, AUDSYS.
USE ANY SQL TRANSLATION PROFILE	Use SQL translation profiles in any schema except SYS, AUDSYS.
DROP ANY SQL TRANSLATION PROFILE	Drop SQL translation profiles in any schema except SYS, AUDSYS.
TRANSLATE ANY SQL	Translate SQL through the grantee's SQL translation profile for any user.
SYNONYMS:	-
CREATE ANY SYNONYM	Create private synonyms in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE SYNONYM privilege.
DROP ANY SYNONYM	Drop private synonyms in any schema except SYS, AUDSYS.
TABLES:	-
CREATE ANY TABLE	Create a table in any schema except SYS, AUDSYS. The owner of the schema containing the table must have space quota on the tablespace to contain the table. If the grantee is the schema owner, then grantee should have been granted CREATE TABLE privilege.
ALTER ANY TABLE	Alter a table or view in any schema except SYS, AUDSYS.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
BACKUP ANY TABLE	Use the Export utility to incrementally export objects from the schema of other users except SYS, AUDSYS.
DELETE ANY TABLE	Delete rows from tables, table partitions, or views in any schema except SYS, AUDSYS.
DROP ANY TABLE	Drop or truncate tables or table partitions in any schema except SYS, AUDSYS.
INSERT ANY TABLE	Insert rows into tables and views in any schema except SYS, AUDSYS.
LOCK ANY TABLE	Lock tables and views in any schema except SYS, AUDSYS.
READ ANY TABLE	Query tables, views, or materialized views in any schema except SYS, AUDSYS.
SELECT ANY TABLE	Query tables, views, or materialized views in any schema except SYS, AUDSYS. Obtain row locks using a SELECT ... FOR UPDATE.
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.
UPDATE ANY TABLE	Update rows in tables and views in any schema except SYS, AUDSYS.
TRIGGERS:	—
CREATE ANY TRIGGER	Create database triggers in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE TRIGGER privilege.
ALTER ANY TRIGGER	Enable, disable, or compile database triggers in any schema except SYS, AUDSYS.
DROP ANY TRIGGER	Drop database triggers in any schema except SYS, AUDSYS.
TYPES:	—
CREATE ANY TYPE	Create object types and object type bodies in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE TYPE privilege.
ALTER ANY TYPE	Alter object types in any schema except SYS, AUDSYS.
DROP ANY TYPE	Drop object types and object type bodies in any schema except SYS, AUDSYS.
EXECUTE ANY TYPE	Use and reference object types and collection types in any schema except SYS, AUDSYS, and invoke methods of an object type in any schema, except SYS, AUDSYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema.
UNDER ANY TYPE	Create subtypes under any nonfinal object types.
VIEWS:	—
CREATE ANY VIEW	Create views in any schema except SYS, AUDSYS. If the grantee is the schema owner, then grantee should have been granted CREATE VIEW privilege.
DROP ANY VIEW	Drop views in any schema except SYS, AUDSYS.
UNDER ANY VIEW	Create subviews under any object views.

Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)

Schema Privilege Name	Operations Authorized
FLASHBACK ANY TABLE	Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.
VIRTUAL PRIVATE DATABASE:	—
EXEMPT ACCESS POLICY	Bypass fine-grained access control. Caution: This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.
ADMINISTER ROW LEVEL SECURITY POLICY	Allow management of Virtual Private Database (VPD) policies in a schema (fine-grained access control, row-level security).
MISCELLANEOUS:	—
ANALYZE ANY	Analyze a table, cluster, or index in any schema except SYS.
COMMENT ANY TABLE	Comment on a table, view, or column in any schema except SYS, AUDSYS.

Table 18-4 Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
ANALYTIC VIEW PRIVILEGES	The following analytic view privileges authorize operations on analytic views.
ALTER	Rename the analytic view.
READ	Query the object with the SELECT statement.
SELECT	Query the object with the SELECT statement.
ATTRIBUTE DIMENSION PRIVILEGES	The following attribute dimension privileges authorize operations on attribute dimensions..
ALTER	Rename the attribute dimension.
DIRECTIVE PRIVILEGES	The object level directive privilege on a user's table allows another user to create a notification directive on it.
DIRECTORY PRIVILEGES	The following directory privileges provide secured access to the files stored in the operating system directory to which the directory object serves as a pointer. The directory object contains the full path name of the operating system directory where the files reside. Because the files are actually stored outside the database, the database server processes also need to have appropriate file permissions on the file system server. Granting object privileges on the directory database object to individual database users, rather than on the operating system, allows the database to enforce security during file operations.
READ	Read files in the directory.
WRITE	Write files in the directory. This privilege is useful only in connection with external tables. It allows the grantee to determine whether the external table agent can write a log file or a bad file to the directory. Restriction: This privilege does not allow the grantee to write to a BFILE.
EXECUTE	Execute a preprocessor program that resides in the directory. A preprocessor program converts data to a supported format when loading data records from an external table with the ORACLE_LOADER access driver. Refer to <i>Oracle AI Database Utilities</i> for more information. This privilege does not implicitly allow READ access on the external table data.

Table 18-4 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
EDITION PRIVILEGE	The following edition privilege authorizes the use of an edition.
USE	Use an edition.
FLASHBACK DATA ARCHIVE PRIVILEGE	The following flashback data archive privilege authorizes operations on flashback data archives.
FLASHBACK ARCHIVE	Enable or disable historical tracking for a table.
HIERARCHY PRIVILEGES	The following hierarchy privileges authorize operations on hierarchies.
ALTER	Rename the hierarchy.
READ	Query the object with the SELECT statement.
SELECT	Query the object with the SELECT statement.
INDEXTYPE PRIVILEGE	The following indextype privilege authorizes operations on indextypes.
EXECUTE	Reference an indextype.
LIBRARY PRIVILEGE	The following library privilege authorizes operations on a library.
EXECUTE	Use and reference the specified object and invoke its methods. Caution: This extremely powerful privilege should be granted only to trusted users. Refer to <i>Oracle AI Database Security Guide</i> before granting this privilege.
MATERIALIZED VIEW PRIVILEGES	The following materialized view privileges authorize operations on a materialized view. The DELETE, INSERT, and UPDATE privileges can be granted only to updatable materialized views.
ON COMMIT REFRESH	Create a refresh-on-commit materialized view on the specified table.
QUERY REWRITE	Create a materialized view for query rewrite using the specified table.
READ	Query the materialized view.
SELECT	Query the materialized view. Obtain row locks with the SELECT ... FOR UPDATE or LOCK TABLE statement.
MINING MODEL PRIVILEGES	The following mining model privileges authorize operations on a mining model. These privileges are not required for models within the users own schema.
ALTER	Change the mining model name or the associated cost matrix using the applicable DBMS_DATA_MINING procedures.
SELECT	Score or view the mining model. Scoring is done with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures.
OBJECT TYPE PRIVILEGES	The following object type privileges authorize operations on a database object type.
DEBUG	Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object type. Place a breakpoint or stop at a line or instruction boundary within the type body.
EXECUTE	Use and reference the specified object and invoke its methods. Access, through a debugger, public variables, types, and methods defined on the object type.
UNDER	Create a subtype under this type. You can grant this object privilege only if you have the UNDER ANY TYPE privilege WITH GRANT OPTION on the immediate supertype of this type.

Table 18-4 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
OLAP PRIVILEGES	The following object privileges are valid if you are using the database with the OLAP option.
INSERT	Insert members into the OLAP cube dimension or measures into the measures folder.
ALTER	Change the definition of the OLAP cube dimension or cube.
DELETE	Delete members from the OLAP cube dimension or measures from the measures folder.
SELECT	View or query the OLAP cube or cube dimension.
UPDATE	Update measure values of the OLAP cube or attribute values of the cube dimension.
OPERATOR PRIVILEGE	The following operator privilege authorizes operations on user-defined operators.
EXECUTE	Reference an operator.
PROCEDURE, FUNCTION, PACKAGE PRIVILEGES	The following procedure, function, and package privileges authorize operations on procedures, functions, and packages. These privileges also apply to Java sources, classes, and resources , which the database treats as though they were procedures for purposes of granting object privileges.
DEBUG	Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object. Place a breakpoint or stop at a line or instruction boundary within the procedure, function, or package. This privilege grants access to the declarations in the method or package specification and body.
EXECUTE	Execute the procedure or function directly, or access any program object declared in the specification of a package, or compile the object implicitly during a call to a currently invalid or uncompiled function or procedure. This privilege does not allow the grantee to explicitly compile using ALTER PROCEDURE or ALTER FUNCTION. For explicit compilation you need the appropriate ALTER system privilege. Access, through a debugger, public variables, types, and methods defined on the procedure, function, or package. This privilege grants access to the declarations in the method or package specification only. Job scheduler objects are created using the DBMS_SCHEDULER package. After these objects are created, you can grant the EXECUTE object privilege on job scheduler classes and programs. You can also grant ALTER privilege on job scheduler jobs, programs, and schedules. Note: Users do not need this privilege to execute a procedure, function, or package indirectly.
PROPERTY GRAPH PRIVILEGES	The following object privileges authorize operations on property graphs.
ALTER	Change the graph definition using ALTER PROPERTY GRAPH statement.
READ	Query the PROPERTY GRAPH with the SELECT statement. Does not allow SELECT ... FOR UPDATE.
SELECT	Query the PROPERTY GRAPH with the SELECT statement.
SCHEDULER PRIVILEGES	Job scheduler objects are created using the DBMS_SCHEDULER package. After these objects are created, you can grant the following privileges.
EXECUTE	Operations on job classes, programs, chains, and credentials.
ALTER	Modifications to jobs, programs, chains, credentials, and schedules.
USE	Associate the specified scheduler resource object with programs and jobs.

Table 18-4 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
SEQUENCE PRIVILEGES	The following sequence privileges authorize operations on a sequence.
ALTER	Change the sequence definition with the ALTER SEQUENCE statement.
KEEP SEQUENCE	The sequence pseudocolumn NEXTVAL retains its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency when replaying after recoverable errors. If this privilege is granted or revoked between runtime and failover of a request, then the original value of NEXTVAL is not retained during replay for Application Continuity for that request. Note: This privilege is not granted by the GRANT ALL PRIVILEGES ON <i>sequence</i> statement. You must explicitly grant this privilege. Note: This privilege is part of the DBA role.
SELECT	Examine and increment values of the sequence with the CURRVAL and NEXTVAL pseudocolumns.
SQL TRANSLATION PROFILE PRIVILEGES	The following SQL translation profile privileges authorize operations on a SQL translation profile.
ALTER	Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile.
USE	Use a SQL translation profile.
SYNONYM PRIVILEGES	Synonym privileges are the same as the privileges for the target object. Granting a privilege on a synonym is equivalent to granting the privilege on the base object. Similarly, granting a privilege on a base object is equivalent to granting the privilege on all synonyms for the object. If you grant to a user a privilege on a synonym, then the user can use either the synonym name or the base object name in the SQL statement that exercises the privilege.
TABLE PRIVILEGES	The following table privileges authorize operations on a table. Any one of following object privileges, except the READ privilege, allows the grantee to lock the table in any lock mode with the LOCK TABLE statement. Note: For external tables, the only valid object privileges are ALTER, READ, and SELECT.
ALTER	Change the table definition with the ALTER TABLE statement.
ASSERTION REFERENCES	Create an assertion that refers to the table. Like REFERENCES this new object privilege needs to be granted directly, i.e., not via a role.
DEBUG	Access, through a debugger: • PL/SQL code in the body of any triggers defined on the table • Information on SQL statements that reference the table directly
DELETE	Remove rows from the table with the DELETE statement. Note: You must grant the SELECT privilege on the table along with the DELETE privilege if the table is on a remote database.
INDEX	Create an index on the table with the CREATE INDEX statement.
INSERT	Add new rows to the table with the INSERT statement. Note: You must grant the SELECT privilege on the table along with the INSERT privilege if the table is on a remote database.
READ	Query the table with the SELECT statement. Does not allow SELECT ... FOR UPDATE.
REFERENCES	Create a constraint that refers to the table. You cannot grant this privilege to a role.

Table 18-4 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
SELECT	To allow access to specific tables during queries, grant the SELECT privilege on the table. Query the table with the SELECT statement, including SELECT ... FOR UPDATE.
UPDATE	Change data in the table with the UPDATE statement. Note: You must grant the SELECT privilege on the table along with the UPDATE privilege if the table is on a remote database.
FLASHBACK	To allow access to a specific table during queries, grant the FLASHBACK privilege on the table. Issue a SQL Flashback Query on the table.
SIGN	A user SCOTT with the SIGN privilege on a blockchain table can sign a row in the blockchain table as a delegate if the following conditions are met: The row does not already have a delegate signature The row does not contain a non-NULL delegate user ID that is different than the ID of user SCOTT.
USER PRIVILEGES	The following privileges authorize operations on a user.
INHERIT PRIVILEGES	Execute invoker's rights procedures or functions owned by the grantee with the privileges of the invoker when the invoker is the user on whom this privilege is granted.
INHERIT REMOTE PRIVILEGES	Allow the user on whom this privilege is granted to execute definer's rights procedures or functions that contain current user database links and are owned by the grantee.
TRANSLATE SQL	Translate SQL through the grantee's SQL translation profile for the user on whom this privilege is granted.
VIEW PRIVILEGES	The following view privileges authorize operations on a view. Any one of the following object privileges, except the READ privilege, allows the grantee to lock the view in any lock mode with the LOCK TABLE statement. To grant a privilege on a view, you must have that privilege with the GRANT OPTION on all of the base tables of the view.
DEBUG	Access, through a debugger: - PL/SQL code in the body of any triggers defined on the view - Information on SQL statements that reference the view directly
DELETE	Remove rows from the view with the DELETE statement.
INSERT	Add new rows to the view with the INSERT statement.
MERGE VIEW	This object privilege has the same behavior as the system privilege MERGE ANY VIEW , except that the privilege is limited to the views specified in the ON clause. For any query issued by the grantee on the specified views, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator.
READ	Query the view with the SELECT statement. Does not allow SELECT ... FOR UPDATE.
REFERENCES	Define foreign key constraints on the view.
SELECT	Query the view with the SELECT statement, including SELECT ... FOR UPDATE. See Also: object_privilege for additional information on granting this object privilege on a view

Table 18-4 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)

Object Privilege Name	Operations Authorized
UNDER	Create a subview under this view. You can grant this object privilege only if you have the UNDER ANY VIEW privilege WITH GRANT OPTION on the immediate superview of this view.
UPDATE	Change data in the view with the UPDATE statement.
FLASHBACK	To allow access to a specific view during queries, grant the FLASHBACK privilege on the view. Issue a SQL Flashback Query on the view.

Examples

Granting a System Privilege to a User: Example

To grant the CREATE SESSION system privilege to the sample user hr, allowing hr to log on to the database, issue the following statement:

```
GRANT CREATE SESSION
  TO hr;
```

Assigning User Passwords When Granting a System Privilege: Example

Assume that user hr exists and user newuser does not exist. The following statement resets the user hr password to *password1*, creates user newuser with *password2*, and grants both users the CREATE SESSION system privilege:

```
GRANT CREATE SESSION
  TO hr, newuser IDENTIFIED BY password1, password2;
```

Granting System Privileges to a Role: Example

The following statement grants appropriate system privileges to a data warehouse manager role, which was created in the "[Creating a Role: Example](#)":

```
GRANT
  CREATE ANY MATERIALIZED VIEW
  , ALTER ANY MATERIALIZED VIEW
  , DROP ANY MATERIALIZED VIEW
  , QUERY REWRITE
  , GLOBAL QUERY REWRITE
  TO dw_manager
  WITH ADMIN OPTION;
```

The dw_manager privilege domain now contains the system privileges related to materialized views.

Granting a Role with the ADMIN OPTION: Example

To grant the dw_manager role with the ADMIN OPTION to the sample user sh, issue the following statement:

```
GRANT dw_manager
  TO sh
  WITH ADMIN OPTION;
```

User sh can now perform the following operations with the dw_manager role:

- Enable the role and exercise any privileges in the privilege domain of the role, including the CREATE MATERIALIZED VIEW system privilege
- Grant and revoke the role to and from other users
- Drop the role
- Grant and revoke the dw_manager role to and from program units in the sh schema

Granting a Role with the DELEGATE OPTION: Example

To grant the dw_manager role with the DELEGATE OPTION to the sample user sh, issue the following statement:

```
GRANT dw_manager
  TO sh
  WITH DELEGATE OPTION;
```

User sh can now grant and revoke the dw_manager role to and from program units in the sh schema.

Granting Object Privileges to a Role: Example

The following example grants the SELECT object privileges to a data warehouse user role, which was created in the "[Creating a Role: Example](#)":

```
GRANT SELECT ON sh.sales TO warehouse_user;
```

Granting a Role to a Role: Example

The following statement grants the warehouse_user role to the dw_manager role. Both roles were created in the "[Creating a Role: Example](#)":

```
GRANT warehouse_user TO dw_manager;
```

The dw_manager role now contains all of the privileges in the domain of the warehouse_user role.

Granting an Object Privilege on a User: Example

To grant the INHERIT PRIVILEGES object privilege on user sh to user hr, issue the following statement:

```
GRANT INHERIT PRIVILEGES ON USER sh TO hr;
```

Granting an Object Privilege on a Directory: Example

To grant READ on directory bfile_dir to user hr, with the GRANT OPTION, issue the following statement:

```
GRANT READ ON DIRECTORY bfile_dir TO hr
  WITH GRANT OPTION;
```

Granting Object Privileges on a Table to a User: Example

To grant all privileges on the table oe.bonuses, which was created in "[Merging into a Table: Example](#)", to the user hr with the GRANT OPTION, issue the following statement:

```
GRANT ALL ON bonuses TO hr
  WITH GRANT OPTION;
```

The user hr can subsequently perform the following operations:

- Exercise any privilege on the bonuses table

- Grant any privilege on the bonuses table to another user or role

Granting Object Privileges on a View: Example

To grant SELECT and UPDATE privileges on the view emp_view, which was created in "[Creating a View: Example](#)", to all users, issue the following statement:

```
GRANT SELECT, UPDATE
  ON emp_view TO PUBLIC;
```

All users can subsequently query and update the view of employee details.

Granting Object Privileges to a Sequence in Another Schema: Example

To grant SELECT privilege on the customers_seq sequence in the schema oe to the user hr, issue the following statement:

```
GRANT SELECT
  ON oe.customers_seq TO hr;
```

The user hr can subsequently generate the next value of the sequence with the following statement:

```
SELECT oe.customers_seq.NEXTVAL
  FROM DUAL;
```

Granting Multiple Object Privileges on Individual Columns: Example

To grant to user oe the REFERENCES privilege on the employee_id column and the UPDATE privilege on the employee_id, salary, and commission_pct columns of the employees table in the schema hr, issue the following statement:

```
GRANT REFERENCES (employee_id),
  UPDATE (employee_id, salary, commission_pct)
  ON hr.employees
  TO oe;
```

The user oe can subsequently update values of the employee_id, salary, and commission_pct columns. User oe can also define referential integrity constraints that refer to the employee_id column. However, because the GRANT statement lists only these columns, oe cannot perform operations on any of the other columns of the employees table.

For example, oe can create a table with a constraint:

```
CREATE TABLE dependent
  (dependno    NUMBER,
   dependname  VARCHAR2(10),
   employee    NUMBER
   CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

The constraint in_emp ensures that all dependents in the dependent table correspond to an employee in the employees table in the schema hr.

GRANT DATA ROLE

Purpose

Use GRANT DATA ROLE to grant one or more data roles to end users, data roles, or application identities.

Prerequisites

To execute this command, you must have the `GRANT ANY DATA ROLE` system privilege.

You can use the `DBA_DATA_ROLE_GRANTS` data dictionary view to query existing data role grants together with their properties, like start time and end time.

Note that data roles that are externally mapped cannot be granted to other end users or data roles within the database. They should be granted to application users or roles through the external identity provider.

Note that there are two distinct usages for data role grants:

- Grant data role to data role or end user so that the grantee can inherit the privileges from the granted data role.
- Grant data role to application identity so that the data role can be enabled by an application during an application session.

You can use the same `GRANT DATA ROLE` statement for one usage or the other. Both usages may not be combined in a single statement. That is, the list of grantees can either be all application identities or no application identities. If a mixture of application identities and data roles or end users are specified, an error is raised (as data roles granted to application identity cannot be granted to other data roles or end users).

Syntax

data_role_list

grantee_list

grantee

Semantics

- **IF EXISTS:** If you specify **IF EXISTS** and the data role exists, then it will be granted to the grantee(s) specified. If the data role does not exist, no error is thrown.
If you do not specify **IF EXISTS**, and the data role exists, then it will be granted to the grantee(s) specified. If the data role does not exist, an error is thrown.
- **data_role_list:** Refers to the names of data roles to be granted. Only local data roles may be granted. A data role granted to a local end user or data role cannot be granted to an application identity.
- **grantee_list:** Refers to the names of the grantees to which the data roles are granted. A grantee can be an end user, an application identity, or a local data role.
- **START TIME:** Refers to the time from which the grant becomes effective, in **TIMESTAMP WITH TIME ZONE** format. This is optional. Not applicable if granting to application identity.
- **END TIME:** Refers to the time on which the grant becomes ineffective, in **TIMESTAMP WITH TIME ZONE** format. This is optional. Not applicable if granting to application identity.

Example

The following SQL statement illustrates granting of the data role *manager_role* to the end user *marvin*:

```
GRANT DATA ROLE manager_role TO marvin;
```

The following SQL statement illustrates granting of the data role *employee_role* to the data role *manager_role*:

```
GRANT DATA ROLE employee_role TO manager_role;
```

INSERT

Purpose

Use the **INSERT** statement to add rows to a table, the base table of a view, a partition of a partitioned table or a subpartition of a composite-partitioned table, or an object table or the base table of an object view.

Prerequisites

For you to insert rows into a table, the table must be in your own schema or you must have the **INSERT** object privilege on the table.

For you to insert rows into the base table of a view, the owner of the schema containing the view must have the **INSERT** object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the **INSERT** object privilege on the view.

If you have the **INSERT ANY TABLE** system privilege, then you can also insert rows into any table or the base table of any view.

You must also have the **READ** or **SELECT** object privilege on the table into which you want to insert rows if the table is on a remote database.

To specify the *returning_clause*, you must have the READ or SELECT object privilege on the object.

If the SQL92_SECURITY initialization parameter is set to TRUE and the INSERT operation references table columns, such as the columns in a *returning_clause*, then you must have the SELECT object privilege on the object into which you want to insert rows.

Conventional and Direct-Path INSERT

You can use the INSERT statement to insert data into a table, partition, or view in two ways: conventional INSERT and direct-path INSERT. When you issue a conventional INSERT statement, the database reuses free space in the table into which you are inserting and maintains referential integrity constraints. With direct-path INSERT, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the existing data is not reused. This alternative enhances performance during insert operations and is similar to the functionality of the Oracle direct-path loader utility, SQL*Loader. When you insert into a table that has been created in parallel mode, direct-path INSERT is the default.

The manner in which the database generates redo and undo data depends in part on whether you are using conventional or direct-path INSERT:

- Conventional INSERT always generates maximal redo and undo for changes to both data and metadata, regardless of the logging setting of the table and the archivelog and force logging settings of the database.
- Direct-path INSERT generates both redo and undo for *metadata* changes, because these are needed for operation recovery. For *data* changes, undo and redo are generated as follows:
 - Direct-path INSERT always bypasses undo generation for data changes.
 - If the database is not in ARCHIVELOG or FORCE LOGGING mode, then no redo is generated for data changes, regardless of the logging setting of the table.
 - If the database is in ARCHIVELOG mode (but not in FORCE LOGGING mode), then direct-path INSERT generates data redo for LOGGING tables but not for NOLOGGING tables.
 - If the database is in ARCHIVELOG **and** FORCE LOGGING mode, then direct-path SQL generate data redo for both LOGGING and NOLOGGING tables.

Direct-path INSERT is subject to a number of restrictions. If any of these restrictions is violated, then the database executes conventional INSERT serially without returning any message, unless otherwise noted:

- You can have multiple direct-path INSERT statements in a single transaction, with or without other DML statements. However, after one DML statement alters a particular table, partition, or index, no other DML statement in the transaction can access that table, partition, or index.
- Queries that access the same table, partition, or index are allowed before the direct-path INSERT statement, but not after it.
- If any serial or parallel statement attempts to access a table that has already been modified by a direct-path INSERT in the same transaction, then the database returns an error and rejects the statement.
- The target table cannot be of a cluster.
- The target table cannot contain object type columns.
- Direct-path INSERT is not supported for an index-organized table (IOT) if it has a mapping table, or if it is reference by a materialized view.

- Direct-path INSERT into a single partition of an index-organized table (IOT), into a partitioned IOT with only one partition, or into an IOT that is not partitioned, will be done serially, even if the IOT was created in parallel mode or you specify the APPEND or APPEND_VALUES hint. However, direct-path INSERT operations into a partitioned IOT will honor parallel mode as long as the partition-extended name is not used and the IOT has more than one partition.
- The target table cannot have any triggers or referential integrity constraints defined on it.
- The target table cannot be replicated.
- A transaction containing a direct-path INSERT statement cannot be or become distributed.

Semantics

hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

For a multi-table insert, if you specify the `PARALLEL` hint for any target table, then the entire multi-table insert statement is parallelized even if the target tables have not been created or altered with `PARALLEL` specified. If you do not specify the `PARALLEL` hint, then the insert operation will not be parallelized unless all target tables were created or altered with `PARALLEL` specified.

① See Also

- "[Hints](#)" for the syntax and description of hints
- "[Restrictions on Multi-Table Inserts](#)"

single_table_insert

In a **single-table insert**, you insert values into one row of a table, view, or materialized view by specifying values explicitly or by retrieving the values through a subquery.

You can use the *flashback_query_clause* in *subquery* to insert past data into *table*. Refer to the [flashback_query_clause](#) of `SELECT` for more information on this clause.

Restriction on Single-Table Inserts

If you retrieve values through a subquery, then the select list of the subquery must have the same number of columns as the column list of the `INSERT` statement. If you omit the column list, then the subquery must provide values for every column in the table.

① See Also

"[Inserting Values into Tables: Examples](#)"

insert_into_clause

Use the `INSERT INTO` clause to specify the target object or objects into which the database is to insert data.

Directory-based sharding uses the same partition extension syntax as system-based sharding.

DML_table_expression_clause

Use the `INTO DML_table_expression_clause` to specify the objects into which data is being inserted.

schema

Specify the schema containing the table, view, or materialized view. If you omit *schema*, then the database assumes the object is in your own schema.

table | view | materialized_view | subquery

Specify the name of the table or object table, view or object view, materialized view, or the column or columns returned by a subquery, into which rows are to be inserted. If you specify a view or object view, then the database inserts rows into the base table of the view.

You cannot insert rows into a read-only materialized view. If you insert rows into a writable materialized view, then the database inserts the rows into the underlying container table. However, the insertions are overwritten at the next refresh operation. If you insert rows into an updatable materialized view that is part of a materialized view group, then the database also inserts the corresponding rows into the master table.

If any value to be inserted is a REF to an object table, and if the object table has a primary key object identifier, then the column into which you insert the REF must be a REF column with a referential integrity or SCOPE constraint to the object table.

If *table*, or the base table of *view*, contains one or more domain index columns, then this statement executes the appropriate indextype insert routine.

Issuing an INSERT statement against a table fires any INSERT triggers defined on the table.

📘 See Also

Oracle AI Database Data Cartridge Developer's Guide for more information on these routines

Restrictions on the *DML_table_expression_clause*

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base table of *view* contains any domain indexes marked IN_PROGRESS or FAILED.
- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.
- With regard to the ORDER BY clause of the *subquery* in the *DML_table_expression_clause*, ordering is guaranteed only for the rows being inserted, and only within each extent of the table. Ordering of new rows with respect to existing rows is not guaranteed.
- If a view was created using the WITH CHECK OPTION, then you can insert into the view only rows that satisfy the defining query of the view.
- If a view was created using a single base table, then you can insert rows into the view and then retrieve those values using the *returning_clause*.
- You cannot insert rows into a view except with INSTEAD OF triggers if the defining query of the view contains one of the following constructs:

A set operator

A DISTINCT operator

An aggregate or analytic function

A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause

A collection expression in a SELECT list

A subquery in a SELECT list

A subquery designated WITH READ ONLY

Joins, with some exceptions, as documented in *Oracle AI Database Administrator's Guide*

- If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the INSERT statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE. Refer to [ALTER SESSION](#) for information on the SKIP_UNUSABLE_INDEXES session parameter.

partition_extension_clause

Specify the name or partition key value of the partition or subpartition within *table*, or the base table of *view*, targeted for inserts.

If a row to be inserted does not map into a specified partition or subpartition, then the database returns an error.

Restriction on Target Partitions and Subpartitions

This clause is not valid for object tables or object views.

① See Also

"[References to Partitioned Tables and Indexes](#)"

dblink

Specify a complete or partial name of a database link to a remote database where the table or view is located.

You can insert rows into a remote table or view only if you are using the database distributed functionality.

To insert rows into a remote table you must have both INSERT and SELECT privileges on the table.

If you omit *dblink*, then the database assumes that the table or view is on the local database. You can insert rows into a local table with just the INSERT privilege.

① Note

Starting with Oracle Database 12c Release 2 (12.2), the INSERT statement accepts remote LOB locators as bind variables. Refer to the "Distributed LOBs" chapter in *Oracle AI Database SecureFiles and Large Objects Developer's Guide* for more information.

① See Also

- "[Syntax for Schema Objects and Parts in SQL Statements](#)" and "[References to Objects in Remote Databases](#)" for information on referring to database links
- "[Inserting into a Remote Database: Example](#)"

subquery_restriction_clause

Use the *subquery_restriction_clause* to restrict the subquery in one of the following ways:

WITH READ ONLY

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify `WITH CHECK OPTION` to indicate that the database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

CONSTRAINT *constraint*

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

① See Also

["Using the WITH CHECK OPTION Clause: Example"](#)

table_collection_expression

The *table_collection_expression* lets you inform Oracle that the value of *collection_expression* should be treated as a table for purposes of query and DML operations. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

① Note

In earlier releases of Oracle, when *collection_expression* was a subquery, *table_collection_expression* was expressed as `THE subquery`. That usage is now deprecated.

① See Also

["Table Collections: Examples"](#)

t_alias

Specify a **correlation name**, which is an alias for the table, view, materialized view, or subquery to be referenced elsewhere in the statement.

Restriction on Table Aliases

You cannot specify *t_alias* during a multi-table insert.

column

Specify a column of the table, view, or materialized view. In the inserted row, each column in this list is assigned a value from the *insert_values_clause* or the subquery. If you want to assign a value to an INVISIBLE column, then you must include the column in this list.

If you omit one or more of the table's columns from this list, then the column value of that column for the inserted row is the column default value as specified when the table was created or last altered. If any omitted column has a NOT NULL constraint and no default value, then the database returns an error indicating that the constraint has been violated and rolls back the INSERT statement. Refer to [CREATE TABLE](#) for more information on default column values.

If you omit the column list altogether, then the *insert_values_clause* or query must specify values for all columns in the table.

insert_values_clause

For a **single-table insert** operation, specify a row of values to be inserted into the table or view. You must specify a value in the *insert_values_clause* for each column in the column list. If you omit the column list, then the *insert_values_clause* must provide values for every column in the table.

You can only supply one set of values for each *insert_into_clause* in a **multi-table insert** operation.

In a **multi-table insert** operation, each expression in the *insert_values_clause* must refer to columns returned by the select list of the subquery. If you omit the *insert_values_clause*, then the select list of the subquery determines the values to be inserted, so it must have the same number of columns as the column list of the corresponding *insert_into_clause*. If you do not specify a column list in the *insert_into_clause*, then the computed row must provide values for all columns in the target table.

For both types of insert operations, if you specify a column list in the *insert_into_clause*, then the database assigns to each column in the list a corresponding value from the values clause or the subquery. You can specify DEFAULT for any value in the *insert_values_clause*. If you have specified a default value for the corresponding column of the table or view, then that value is inserted. If no default value for the corresponding column has been specified, then the database inserts null. Refer to "[About SQL Expressions](#)" and [SELECT](#) for syntax of valid expressions.

Restrictions on Inserted Values

Values are subject to the following restrictions:

- You cannot insert a BFILE value until you have initialized the BFILE locator to null or to a directory name and filename.
- When inserting into a list-partitioned table, you cannot insert a value into the partitioning key column that does not already exist in the *partition_key_value* list of one of the partitions.
- You cannot specify DEFAULT when inserting into a view.
- If you insert string literals into a RAW column, then during subsequent queries the database will perform a full table scan rather than using any index that might exist on the RAW column.
- You cannot use default values for columns in row value expressions.

Inserting multiple default values into an identity column using the table value constructor results in the following error : Sequence as default is not supported with INSERT using table value constructor .

- "[Inserting into a Substitutable Tables and Columns: Examples](#)", "[Inserting Using the TO_LOB Function: Example](#)", "[Inserting Sequence Values: Example](#)", and "[Inserting Using Bind Variables: Example](#)"

returning_clause

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a *returning_clause* can retrieve column expressions using the affected row, rowid, and REFS to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning_clause* stores values from expressions, rowids, and REFS involving the affected rows in bind arrays.

expr

Each item in the *expr* list must be a valid expression syntax.

INTO

The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data_item* list.

data_item

Each *data_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

Restrictions

The following restrictions apply to the RETURNING clause:

- The *expr* is restricted as follows:
 - For UPDATE and DELETE statements each *expr* must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same *returning_clause*. For INSERT statements, each *expr* must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
 - Single-set aggregate function expressions cannot include the DISTINCT keyword.

- If the *expr* list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the *returning_clause* for a multi-table insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve LONG types with this clause.
- You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

📘 See Also

Oracle AI Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables

insert_set_clause

Each *column_value_pairs* corresponds to a single row in INSERT.

You can insert a single row by specifying *column_value_pairs* with or without parentheses.

To insert multiple rows you must use parentheses.

Example 1: Single Row Insert without Parentheses

```
INSERT INTO employees SET
  employee_id = 210, last_name = 'Smith', email = 'ASMITH', hire_date = SYSDATE, job_id
= 'AD_ASST';
```

Example 2: Single Row Insert with Parentheses

```
INSERT INTO employees SET
  (employee_id = 210, last_name = 'Smith', email = 'ASMITH', hire_date = SYSDATE,
  job_id = 'AD_ASST');
```

Example 3: Multi Row Insert

```
INSERT INTO employees SET
  (employee_id = 210, last_name = 'Smith', email = 'ASMITH', hire_date = SYSDATE,
  job_id = 'AD_ASST'),
  (employee_id = 211, last_name = 'Roddick', email = 'ARODDICK', hire_date = SYSDATE,
  job_id = 'IT_PROG');
```

by_name_position_clause

by_name_position_clause enables support for non-positional insert with a subquery, where the exposed column names (alias or simple column name, if unaliased) in the subquery's select list are matched against the column names of the target table, to determine the order that values should be inserted into the table.

As a modifier for a subquery, *by_name_position_clause* can appear anywhere before a subquery optionally.

The following two insert statements are semantically equivalent:

```
INSERT INTO job_history
```

```
BY NAME
SELECT employee_id, hire_date AS start_date, SYSDATE - 1 AS end_date, department_id,
       job_id FROM employees
WHERE employee_id = 206
```

```
INSERT INTO job_history (employee_id, start_date, end_date, department_id, job_id)
SELECT employee_id, hire_date, SYSDATE - 1, department_id, job_id FROM employees
WHERE employee_id = 206;
```

If the matching column in the target table cannot be found, an error is raised.

multi_table_insert

In a **multi-table insert**, you insert rows returned from the evaluation of a subquery into one or more tables.

Table aliases are not defined by the select list of the subquery. Therefore, they are not visible in the clauses dependent on the select list. For example, this can happen when trying to refer to an object column in an expression. To use an expression with a table alias, you must put the expression into the select list with a column alias, and then refer to the column alias in the VALUES clause or WHEN condition of the multi-table insert.

ALL into_clause

Specify ALL followed by multiple *insert_into_clauses* to perform an **unconditional multi-table insert**. The database executes each *insert_into_clause* once for each row returned by the subquery.

Restrictions Using INSERT ALL

- The maximum number of rows you can insert into a table with 4096 columns is 15.
- The maximum number of rows you can insert into a table with 1000 columns is 65.
- The maximum row limit for tables with fewer columns is not constant and may vary.

You cannot use a subquery with *insert_value_clause* and *insert_set_clause* in *multi_table_insert*.

conditional_insert_clause

Specify the *conditional_insert_clause* to perform a **conditional multi-table insert**.

You can only supply one set of values for each WHEN or ELSE clause of *conditional_insert_clause*.

You cannot use a subquery with *insert_value_clause* and *insert_set_clause* in *conditional_insert_clause*.

The database filters each *insert_into_clause* through the corresponding WHEN condition, which determines whether that *insert_into_clause* is executed. Each expression in the WHEN condition must refer to columns returned by the select list of the subquery. A single multi-table insert statement can contain up to 127 WHEN clauses.

ALL

If you specify ALL, the default value, then the database evaluates each WHEN clause regardless of the results of the evaluation of any other WHEN clause. For each WHEN clause whose condition evaluates to true, the database executes the corresponding INTO clause list.

FIRST

If you specify **FIRST**, then the database evaluates each **WHEN** clause in the order in which it appears in the statement. For the first **WHEN** clause that evaluates to true, the database executes the corresponding **INTO** clause and skips subsequent **WHEN** clauses for the given row.

ELSE clause

For a given row, if no **WHEN** clause evaluates to true, then:

- If you have specified an **ELSE** clause, then the database executes the **INTO** clause list associated with the **ELSE** clause.
- If you did not specify an **else** clause, then the database takes no action for that row.

① See Also

["Multi-Table Inserts: Examples"](#)

Restrictions on Multi-Table Inserts

multi-table inserts are subject to the following restrictions:

- You can perform multi-table inserts only on tables, not on views or materialized views.
- You cannot perform a multi-table insert into a remote table.
- You cannot specify a **TABLE** collection expression when performing a multi-table insert.
- multi-table inserts are not parallelized if any target table is index organized or if any target table has a bitmap index defined on it.
- Plan stability is not supported for multi-table insert statements.
- The subquery of the multitable insert statement cannot use a sequence. For rules pertaining to sequences, see [How to Use Sequence Values](#)

subquery

Specify a subquery that returns rows that are inserted into the table. The subquery can refer to any table, view, or materialized view, including the target tables of the **INSERT** statement. If the subquery selects no rows, then the database inserts no rows into the table.

You can use *subquery* in combination with the **T0_LOB** function to convert the values in a **LONG** column to **LOB** values in another column in the same or another table.

- To migrate **LONG** values to **LOB** values in another column in a view, you must perform the migration on the base table and then add the **LOB** column to the view.
- To migrate **LONG** values on a remote table to **LOB** values in a local table, you must perform the migration on the remote table using the **T0_LOB** function, and then perform an **INSERT ... subquery** operation to copy the **LOB** values from the remote table into the local table.

Notes on Inserting with a Subquery

The following notes apply when inserting with a subquery:

- If *subquery* returns the partial or total equivalent of a materialized view, then the database may use the materialized view for query rewrite in place of one or more tables specified in *subquery*.

① See Also

Oracle AI Database Data Warehousing Guide for more information on materialized views and query rewrite

- If *subquery* refers to remote objects, then the INSERT operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the *subquery* in the *DML_table_expression_clause* refers to any remote objects, then the INSERT operation will run serially without notification. See [parallel_clause](#) for more information.
- If *subquery* includes an ORDER BY clause, then it will override row ordering specified using attribute clustering table properties.

① See Also

- ["Inserting Values with a Subquery: Example"](#)
- [BFILENAME](#) for an example of inserting into a BFILE
- *Oracle AI Database SecureFiles and Large Objects Developer's Guide* for information on initializing BFILES
- ["About SQL Expressions "](#) and [SELECT](#) for syntax of valid expressions

wait_clause

The NOWAIT and WAIT clauses let you tell the database how to proceed if a transaction attempts to lock a row that is locked by another transaction.

Specify NOWAIT to rollback the DML statement immediately, if a lock exists.

Specify WAIT to instruct the database to wait *integer* SECONDS, MILLISECONDS, or MICROSECONDS. Seconds is the default.

Specify WAIT FOREVER to instruct the database to retain its default behavior of waiting for row locks indefinitely.

If you specify neither WAIT nor NOWAIT, then the database waits until the row is available and then returns the results of the particular DML operation.

error_logging_clause

The *error_logging_clause* lets you capture DML errors and the log column values of the affected rows and save them in an error logging table.

INTO table

Specify the name of the error logging table. If you omit this clause, then the database assigns the default name generated by the DBMS_ERRLOG package. The default error log table name is ERR\$_ followed by the first 25 characters of the name of the table upon which the DML operation is being executed.

simple_expression

Specify the value to be used as a statement tag, so that you can identify the errors from this statement in the error logging table. The expression can be either a text literal, a number literal,

or a general SQL expression such as a bind variable. You can also use a function expression if you convert it to a text literal — for example, `TO_CHAR(SYSDATE)`.

REJECT LIMIT

This clause lets you specify an integer as an upper limit for the number of errors to be logged before the statement terminates and rolls back any changes made by the statement. The default rejection limit is zero. For parallel DML operations, the reject limit is applied to each parallel server.

Restrictions on DML Error Logging

- The following conditions cause the statement to fail and roll back without invoking the error logging capability:
 - Violated deferred constraints.
 - Any direct-path INSERT or MERGE operation that raises a unique constraint or index violation.
 - Any update operation UPDATE or MERGE that raises a unique constraint or index violation.
- You cannot track errors in the error logging table for LONG, LOB, or object type columns. However, the table that is the target of the DML operation can contain these types of columns.
 - If you create or modify the corresponding error logging table so that it contains a column of an unsupported type, and if the name of that column corresponds to an unsupported column in the target DML table, then the DML statement fails at parse time.
 - If the error logging table does not contain any unsupported column types, then all DML errors are logged until the reject limit of errors is reached. For rows on which errors occur, column values with corresponding columns in the error logging table are logged along with the control information.
- You cannot use *error_logging_clause* with SQL assertions.

Examples

Inserting Values into Tables: Examples

The following statement inserts a row into the sample table `departments`:

```
INSERT INTO departments
VALUES (280, 'Recreation', 121, 1700);
```

If the `departments` table had been created with a default value of 121 for the `manager_id` column, then you could issue the same statement as follows:

```
INSERT INTO departments
VALUES (280, 'Recreation', DEFAULT, 1700);
```

The following statement inserts a row with six columns into the employees table. One of these columns is assigned NULL and another is assigned a number in scientific notation:

```
INSERT INTO employees (employee_id, last_name, email,
    hire_date, job_id, salary, commission_pct)
VALUES (207, 'Gregory', 'pgregory@example.com',
    sysdate, 'PU_CLERK', 1.2E3, NULL);
```

The following statement has the same effect as the preceding example, but uses a subquery in the *DML_table_expression_clause*:

```
INSERT INTO
(SELECT employee_id, last_name, email, hire_date, job_id,
    salary, commission_pct FROM employees)
VALUES (207, 'Gregory', 'pgregory@example.com',
    sysdate, 'PU_CLERK', 1.2E3, NULL);
```

Inserting Values with a Subquery: Example

The following statement copies employees whose commission exceeds 25% of their salary into the bonuses table, which was created in "[Merging into a Table: Example](#)":

```
INSERT INTO bonuses
SELECT employee_id, salary*1.1
FROM employees
WHERE commission_pct > 0.25;
```

Inserting Into a Table with Error Logging: Example

The following statements create a raises table in the sample schema hr, create an error logging table using the DBMS_ERRLOG package, and populate the raises table with data from the employees table. One of the inserts violates the check constraint on raises, and that row can be seen in errlog. If more than ten errors had occurred, then the statement would have aborted, rolling back any insertions made:

```
CREATE TABLE raises (emp_id NUMBER, sal NUMBER
    CONSTRAINT check_sal CHECK(sal > 8000));

EXECUTE DBMS_ERRLOG.CREATE_ERROR_LOG('raises', 'errlog');

INSERT INTO raises
SELECT employee_id, salary*1.1 FROM employees
WHERE commission_pct > .2
LOG ERRORS INTO errlog ('my_bad') REJECT LIMIT 10;

SELECT ORA_ERR_MESG$, ORA_ERR_TAG$, emp_id, sal FROM errlog;
```

ORA_ERR_MESG\$	ORA_ERR_TAG\$	EMP_ID	SAL
ORA-02290: check constraint my_bad (HR.SYS_C004266) violated		161	7700

Inserting into a Remote Database: Example

The following statement inserts a row into the employees table owned by the user hr on the database accessible by the database link remote:

```
INSERT INTO employees@remote
VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
```

```
TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SH_CLERK', 3000,  
NULL, 121, 20);
```

Inserting Sequence Values: Example

The following statement inserts a new row containing the next value of the departments_seq sequence into the departments table:

```
INSERT INTO departments  
VALUES (departments_seq.nextval, 'Entertainment', 162, 1400);
```

Inserting Using Bind Variables: Example

The following example returns the values of the inserted rows into output bind variables :bnd1 and :bnd2. The bind variables must first be declared.

```
INSERT INTO employees  
(employee_id, last_name, email, hire_date, job_id, salary)  
VALUES  
(employees_seq.nextval, 'Doe', 'john.doe@example.com',  
SYSDATE, 'SH_CLERK', 2400)  
RETURNING salary*12, job_id INTO :bnd1, :bnd2;
```

Inserting into a Substitutable Tables and Columns: Examples

The following example inserts into the persons table, which is created in "[Substitutable Table and Column Examples](#)". The first statement uses the root type person_t. The second insert uses the employee_t subtype of person_t, and the third insert uses the part_time_emp_t subtype of employee_t:

```
INSERT INTO persons VALUES (person_t('Bob', 1234));  
INSERT INTO persons VALUES (employee_t('Joe', 32456, 12, 100000));  
INSERT INTO persons VALUES (  
part_time_emp_t('Tim', 5678, 13, 1000, 20));
```

The following example inserts into the books table, which was created in "[Substitutable Table and Column Examples](#)". Notice that specification of the attribute values is identical to that for the substitutable table example:

```
INSERT INTO books VALUES (  
'An Autobiography', person_t('Bob', 1234));  
INSERT INTO books VALUES (  
'Business Rules', employee_t('Joe', 3456, 12, 10000));  
INSERT INTO books VALUES (  
'Mixing School and Work',  
part_time_emp_t('Tim', 5678, 13, 1000, 20));
```

You can extract data from substitutable tables and columns using built-in functions and conditions. For examples, see the functions [TREAT](#) and [SYS_TYPEID](#), and "[IS OF type Condition](#)".

Inserting Using the TO_LOB Function: Example

The following example copies LONG data to a LOB column in the following long_tab table:

```
CREATE TABLE long_tab (pic_id NUMBER, long_pics LONG RAW);
```

First you must create a table with a LOB.

```
CREATE TABLE lob_tab (pic_id NUMBER, lob_pics BLOB);
```

Next, use an INSERT ... SELECT statement to copy the data in all rows for the LONG column into the newly created LOB column:

```
INSERT INTO lob_tab
  SELECT pic_id, TO_LOB(long_pics) FROM long_tab;
```

When you are confident that the migration has been successful, you can drop the long_pics table. Alternatively, if the table contains other columns, then you can simply drop the LONG column from the table as follows:

```
ALTER TABLE long_tab DROP COLUMN long_pics;
```

Multi-Table Inserts: Examples

The following example uses the multi-table insert syntax to insert into the sample table sh.sales some data from an input table with a different structure.

Note

A number of NOT NULL constraints on the sales table have been disabled for purposes of this example, because the example ignores a number of table columns for the sake of brevity.

The input table looks like this:

```
SELECT * FROM sales_input_table;
```

PRODUCT_ID	CUSTOMER_ID	WEEKLY_ST	SALES_SUN	SALES_MON	SALES_TUE	SALES_WED	SALES_THU	SALES_FRI	SALES_SAT
111	222	01-OCT-00	100	200	300	400	500	600	700
222	333	08-OCT-00	200	300	400	500	600	700	800
333	444	15-OCT-00	300	400	500	600	700	800	900

The multi-table insert statement looks like this:

```
INSERT ALL
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date, sales_sun)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+1, sales_mon)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+2, sales_tue)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+3, sales_wed)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+4, sales_thu)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+5, sales_fri)
  INTO sales (prod_id, cust_id, time_id, amount)
  VALUES (product_id, customer_id, weekly_start_date+6, sales_sat)
  SELECT product_id, customer_id, weekly_start_date, sales_sun,
    sales_mon, sales_tue, sales_wed, sales_thu, sales_fri, sales_sat
  FROM sales_input_table;
```

Assuming these are the only rows in the sales table, the contents now look like this:

```
SELECT * FROM sales
  ORDER BY prod_id, cust_id, time_id;
```

PROD_ID	CUST_ID	TIME_ID	C	PROMO_ID	QUANTITY_SOLD	AMOUNT	COST
111	222	01-OCT-00				100	
111	222	02-OCT-00				200	
111	222	03-OCT-00				300	
111	222	04-OCT-00				400	
111	222	05-OCT-00				500	
111	222	06-OCT-00				600	
111	222	07-OCT-00				700	
222	333	08-OCT-00				200	
222	333	09-OCT-00				300	
222	333	10-OCT-00				400	
222	333	11-OCT-00				500	
222	333	12-OCT-00				600	
222	333	13-OCT-00				700	
222	333	14-OCT-00				800	
333	444	15-OCT-00				300	
333	444	16-OCT-00				400	
333	444	17-OCT-00				500	
333	444	18-OCT-00				600	
333	444	19-OCT-00				700	
333	444	20-OCT-00				800	
333	444	21-OCT-00				900	

The next examples insert into multiple tables. Suppose you want to provide to sales representatives some information on orders of various sizes. The following example creates tables for small, medium, large, and special orders and populates those tables with data from the sample table `oe.orders`:

```
CREATE TABLE small_orders
  (order_id      NUMBER(12) NOT NULL,
   customer_id   NUMBER(6)  NOT NULL,
   order_total   NUMBER(8,2),
   sales_rep_id  NUMBER(6)
  );

CREATE TABLE medium_orders AS SELECT * FROM small_orders;

CREATE TABLE large_orders AS SELECT * FROM small_orders;

CREATE TABLE special_orders
  (order_id      NUMBER(12) NOT NULL,
   customer_id   NUMBER(6)  NOT NULL,
   order_total   NUMBER(8,2),
   sales_rep_id  NUMBER(6),
   credit_limit  NUMBER(9,2),
   cust_email    VARCHAR2(40)
  );
```

The first multi-table insert populates only the tables for small, medium, and large orders:

```
INSERT ALL
  WHEN order_total <= 100000 THEN
    INTO small_orders
  WHEN order_total > 100000 AND order_total <= 200000 THEN
    INTO medium_orders
  WHEN order_total > 200000 THEN
    INTO large_orders
  SELECT order_id, order_total, sales_rep_id, customer_id
  FROM orders;
```

You can accomplish the same thing using the ELSE clause in place of the insert into the large_orders table:

```
INSERT ALL
  WHEN order_total <= 100000 THEN
    INTO small_orders
  WHEN order_total > 100000 AND order_total <= 200000 THEN
    INTO medium_orders
  ELSE
    INTO large_orders
  SELECT order_id, order_total, sales_rep_id, customer_id
  FROM orders;
```

The next example inserts into the small, medium, and large tables, as in the preceding example, and also puts orders greater than 290,000 into the special_orders table. This table also shows how to use column aliases to simplify the statement:

```
INSERT ALL
  WHEN otvl <= 100000 THEN
    INTO small_orders
      VALUES(oid, otvl, sid, cid)
  WHEN otvl > 100000 and otvl <= 200000 THEN
    INTO medium_orders
      VALUES(oid, otvl, sid, cid)
  WHEN otvl > 200000 THEN
    into large_orders
      VALUES(oid, otvl, sid, cid)
  WHEN otvl > 290000 THEN
    INTO special_orders
  SELECT o.order_id oid, o.customer_id cid, o.order_total otvl,
    o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
  FROM orders o, customers c
  WHERE o.customer_id = c.customer_id;
```

Finally, the next example uses the FIRST clause to put orders greater than 290,000 into the special_orders table and exclude those orders from the large_orders table:

```
INSERT FIRST
  WHEN otvl <= 100000 THEN
    INTO small_orders
      VALUES(oid, otvl, sid, cid)
  WHEN otvl > 100000 and otvl <= 200000 THEN
    INTO medium_orders
      VALUES(oid, otvl, sid, cid)
  WHEN otvl > 290000 THEN
    INTO special_orders
  WHEN otvl > 200000 THEN
    INTO large_orders
      VALUES(oid, otvl, sid, cid)
  SELECT o.order_id oid, o.customer_id cid, o.order_total otvl,
    o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
  FROM orders o, customers c
  WHERE o.customer_id = c.customer_id;
```

Inserting Multiple Rows Using a Single Statement: Example

The following statements create three tables named people, patients and staff:

```
CREATE TABLE people (
  person_id  INTEGER NOT NULL PRIMARY KEY,
  given_name VARCHAR2(100) NOT NULL,
  family_name VARCHAR2(100) NOT NULL,
```

```

        title          VARCHAR2(20),
        birth_date     DATE
    );

CREATE TABLE patients (
    patient_id         INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    last_admission_date DATE
);

CREATE TABLE staff (
    staff_id  INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    hired_date DATE
);

```

The following statement inserts a row into the people table:

```

INSERT INTO people
VALUES (1, 'Dave', 'Badger', 'Mr', date'1960-05-01');

```

The following statement returns an error as there is no value provided for the birth_date column:

```

INSERT INTO people
VALUES (2, 'Simon', 'Fox', 'Mr');

```

The following statement inserts a row into the people table:

```

INSERT INTO people (person_id, given_name, family_name, title)
VALUES (2, 'Simon', 'Fox', 'Mr');

```

The following statement inserts a row into the people table and the value for the title column is populated by selecting a static value from the dual table:

```

INSERT INTO people (person_id, given_name, family_name, title)
VALUES (3, 'Dave', 'Frog', (SELECT 'Mr' FROM dual));

```

The following statement inserts multiple rows into the people table using SELECT statement:

```

INSERT INTO people (person_id, given_name, family_name, title)
WITH names AS (
    SELECT 4, 'Ruth',      'Fox',      'Mrs'   FROM dual UNION ALL
    SELECT 5, 'Isabelle', 'Squirrel', 'Miss'  FROM dual UNION ALL
    SELECT 6, 'Justin',   'Frog',     'Master' FROM dual UNION ALL
    SELECT 7, 'Lisa',     'Owl',      'Dr'    FROM dual
)
SELECT * FROM names;

```

The following statement rolls back all the previous DML operations:

```

ROLLBACK;

```

The following statement inserts multiple rows into the people table using 'SELECT' statement with a 'WHERE' condition:

```

INSERT INTO people (person_id, given_name, family_name, title)
WITH names AS (
    SELECT 4, 'Ruth',      'Fox' family_name,      'Mrs'   FROM dual UNION ALL
    SELECT 5, 'Isabelle', 'Squirrel' family_name, 'Miss'  FROM dual UNION ALL
    SELECT 6, 'Justin',   'Frog' family_name,      'Master' FROM dual UNION ALL
    SELECT 7, 'Lisa',     'Owl' family_name,      'Dr'    FROM dual
)
SELECT * FROM names
WHERE family_name LIKE 'F%';

```

The following statement rolls back all the previous DML operations:

```
ROLLBACK;
```

The following statement inserts multiple rows into people, patients and staff table using 'INSERT ALL' statement:

```
INSERT ALL
  /* Every one is a person */
  INTO people (person_id, given_name, family_name, title)
    VALUES (id, given_name, family_name, title)
  INTO patients (patient_id, last_admission_date)
    VALUES (id, admission_date)
  INTO staff (staff_id, hired_date)
    VALUES (id, hired_date)
  WITH names AS (
    SELECT 4 id, 'Ruth' given_name, 'Fox' family_name, 'Mrs' title,
           NULL hired_date, DATE'2009-12-31' admission_date
    FROM   dual UNION ALL
    SELECT 5 id, 'Isabelle' given_name, 'Squirrel' family_name, 'Miss' title ,
           NULL hired_date, DATE'2014-01-01' admission_date
    FROM   dual UNION ALL
    SELECT 6 id, 'Justin' given_name, 'Frog' family_name, 'Master' title,
           NULL hired_date, DATE'2015-04-22' admission_date
    FROM   dual UNION ALL
    SELECT 7 id, 'Lisa' given_name, 'Owl' family_name, 'Dr' title,
           DATE'2015-01-01' hired_date, NULL admission_date
    FROM   dual
  )
  SELECT * FROM names;
```

The following statement rolls back all the previous DML operations:

```
ROLLBACK;
```

The following statement inserts multiple rows into people, patients and staff table using 'INSERT ALL' statement with various conditions:

```
INSERT ALL
  /* Everyone is a person, so insert all rows into people */
  WHEN 1=1 THEN
    INTO people (person_id, given_name, family_name, title)
      VALUES (id, given_name, family_name, title)
  /* Only people with an admission date are patients */
  WHEN admission_date IS NOT NULL THEN
    INTO patients (patient_id, last_admission_date)
      VALUES (id, admission_date)
  /* Only people with a hired date are staff */
  WHEN hired_date IS NOT NULL THEN
    INTO staff (staff_id, hired_date)
      VALUES (id, hired_date)
  WITH names AS (
    SELECT 4 id, 'Ruth' given_name, 'Fox' family_name, 'Mrs' title,
           NULL hired_date, DATE'2009-12-31' admission_date
    FROM   dual UNION ALL
    SELECT 5 id, 'Isabelle' given_name, 'Squirrel' family_name, 'Miss' title ,
           NULL hired_date, DATE'2014-01-01' admission_date
    FROM   dual UNION ALL
    SELECT 6 id, 'Justin' given_name, 'Frog' family_name, 'Master' title,
           NULL hired_date, DATE'2015-04-22' admission_date
    FROM   dual UNION ALL
    SELECT 7 id, 'Lisa' given_name, 'Owl' family_name, 'Dr' title,
           DATE'2015-01-01' hired_date, NULL admission_date
```

```

        FROM dual
    )
    SELECT * FROM names;

```

Insert Using Wait: Example

Note: AUTOCOMMIT is OFF.

Fork 2 sessions and run the commands alternatively in each as follows:

Session 1:

```

INSERT INTO t5 VALUES ('k',0);
1 row created.

```

Session 2:

```

INSERT INTO t5 VALUES ('k',0) WAIT 10;

```

The statement fails after waiting 10 seconds. Error messages:

```

ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",
Description: "Lock held by a transaction to allow other transactions to wait
for it") because it is currently held by another session. The resource being
locked can be identified by 262148 ("usn<<16 | slot") and 1428 ("sequence")
ORA-40097: Failure to acquire row lock, currently held by transaction ID 4.4.1428

```

Session 1:

```

COMMIT;
Commit complete.
SELECT * FROM t5;
C1    C2
-----
K      0

```

Session 2:

```

SELECT * FROM t5;
C1    C2
-----
K      0

```

Insert Using NOWAIT: Example

Session 1:

```

INSERT INTO t5 VALUES ('k',0);
1 row created.

```

Session 2:

```
INSERT INTO t5 VALUES ('k',0) NOWAIT;
```

The statement fails immediately on detecting a row lock. The following error messages appear:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",  
Description: "Lock held by a transaction to allow other transactions to wait  
for it") because it is currently held by another session. The resource being  
locked can be identified by 262148 ("usn<<16 | slot") and 1428 ("sequence")  
ORA-40097: Failure to acquire row lock, currently held by transaction ID 4.4.1428
```

Inserting into a Remote Database: Example

You can insert into an Iceberg table using `INSERT ... SELECT`, where the `SELECT` is run against any Oracle tables or external tables.

The target of the `INSERT` statement can be an Iceberg table in a remote catalog that is mounted on the database using Data Studio. The Iceberg table may be created from the database, or an external Iceberg engine.

- `CREATE ICEBERG TABLE` of the *SQL Language Reference*.

LOCK TABLE

Purpose

Use the `LOCK TABLE` statement to lock one or more tables, table partitions, or table subpartitions in a specified mode. This lock manually overrides automatic locking and permits or denies access to a table or view by other users for the duration of your operation.

Some forms of locks can be placed on the same table at the same time. Other locks allow only one lock for a table.

A locked table remains locked until you either commit your transaction or roll it back, either entirely or to a savepoint before you locked the table.

A lock never prevents other users from querying the table. A query never places a lock on a table. Readers never block writers and writers never block readers.

See Also

- *Oracle Database Concepts* for a complete description of the interaction of lock modes
- [COMMIT](#)
- [ROLLBACK](#)
- [SAVEPOINT](#)

Prerequisites

The table or view must be in your own schema, or you must have the LOCK ANY TABLE system privilege, or you must have any object privilege (except the READ object privilege) on the table or view.

Syntax

lock_table::=

partition_extension_clause::=

**Semantics*****schema***

Specify the schema containing the table or view. If you omit *schema*, then Oracle Database assumes the table or view is in your own schema.

table | view

Specify the name of the table or view to be locked.

If you specify *view*, then Oracle Database locks the base tables of the view.

If you specify the *partition_extension_clause*, then Oracle Database first acquires an implicit lock on the table. The table lock is the same as the lock you specify for the partition or subpartition, with two exceptions:

- If you specify a SHARE lock for the subpartition, then the database acquires an implicit ROW SHARE lock on the table.
- If you specify an EXCLUSIVE lock for the subpartition, then the database acquires an implicit ROW EXCLUSIVE lock on the table.

If you specify PARTITION and *table* is composite-partitioned, then the database acquires locks on all the subpartitions of the partition.

Restrictions on Locking Tables

The following restrictions apply to locking tables:

- If *view* is part of a hierarchy, then it must be the root of the hierarchy.
- You can acquire locks on only the existing partitions in an automatic list-partitioned table. That is, when you specify the following statement, the partition key value must correspond to a partition that already exists in the table; it cannot correspond to a partition that might be created on-demand at a later time:

```
LOCK TABLE ... PARTITION FOR (partition_key_value) ...
```

dblink

Specify a database link to a remote Oracle Database where the table or view is located. You can lock tables and views on a remote database only if you are using Oracle distributed functionality. All tables locked by a LOCK TABLE statement must be on the same database.

If you omit *dblink*, then Oracle Database assumes the table or view is on the local database.

① See Also

"[References to Objects in Remote Databases](#)" for information on specifying database links

***lockmode* Clause**

Specify one of the following modes:

ROW SHARE

ROW SHARE permits concurrent access to the locked table but prohibits users from locking the entire table for exclusive access. ROW SHARE is synonymous with SHARE UPDATE, which is included for compatibility with earlier versions of Oracle Database.

ROW EXCLUSIVE

ROW EXCLUSIVE is the same as ROW SHARE, but it also prohibits locking in SHARE mode. ROW EXCLUSIVE locks are automatically obtained when updating, inserting, or deleting.

SHARE UPDATE

See [ROW SHARE](#).

SHARE

SHARE permits concurrent queries but prohibits updates to the locked table.

SHARE ROW EXCLUSIVE

SHARE ROW EXCLUSIVE is used to look at a whole table and to allow others to look at rows in the table but to prohibit others from locking the table in SHARE mode or from updating rows.

EXCLUSIVE

EXCLUSIVE permits queries on the locked table but prohibits any other activity on it.

NOWAIT

Specify NOWAIT if you want the database to return control to you immediately if the specified table, partition, or table subpartition is already locked by another user. In this case, the database returns a message indicating that the table, partition, or subpartition is already locked by another user.

WAIT

Use the WAIT clause to indicate that the LOCK TABLE statement should wait up to the specified number of seconds to acquire a DML lock. There is no limit on the value of *integer*.

If you specify neither NOWAIT nor WAIT, then the database waits indefinitely until the table is available, locks it, and returns control to you. When the database is executing DDL statements concurrently with DML statements, a timeout or deadlock can sometimes result. The database detects such timeouts and deadlocks and returns an error.

① See Also

Oracle Database Administrator's Guide for more information about locking tables

Examples

Locking a Table: Example

The following statement locks the employees table in exclusive mode but does not wait if another user already has locked the table:

```
LOCK TABLE employees
  IN EXCLUSIVE MODE
  NOWAIT;
```

The following statement locks the remote employees table that is accessible through the database link remote:

```
LOCK TABLE employees@remote
  IN SHARE MODE;
```

SQL Statements: MERGE to UPDATE

This chapter contains the following SQL statements:

- [MERGE](#)
- [NOAUDIT \(Traditional Auditing\)](#)
- [NOAUDIT \(Unified Auditing\)](#)
- [PURGE](#)
- [RENAME](#)
- [REVOKE](#)
- [ROLLBACK](#)
- [SAVEPOINT](#)
- [SELECT](#)
- [SET CONSTRAINT\[S\]](#)
- [SET ROLE](#)
- [SET TRANSACTION](#)
- [TRUNCATE CLUSTER](#)
- [TRUNCATE TABLE](#)
- [UPDATE](#)

MERGE

Purpose

Use the MERGE statement to select rows from one or more sources for update or insertion into a table or view. You can specify conditions to determine whether to update or insert into the target table or view.

This statement is a convenient way to combine multiple operations. It lets you avoid multiple INSERT, UPDATE, and DELETE DML statements.

MERGE is a deterministic statement. You cannot update the same row of the target table multiple times in the same MERGE statement.

Note

In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the MERGE INTO statement, the MERGE INTO statement would be prevented with an ORA-28132: Merge into syntax does not support security policies error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include MERGE INTO operations. To do so, in the DBMS_RLS.ADD_POLICY statement_types parameter, include the INSERT, UPDATE, and DELETE statements, or just omit the statement_types parameter altogether. Refer to *Oracle AI Database Security Guide* for more information on enforcing policies on specific SQL statement types.

Prerequisites

You must have the INSERT and UPDATE object privileges on the target table and the SELECT object privilege on the source objects. To specify the DELETE clause of the *merge_update_clause*, you must also have the DELETE object privilege on the target table or view.

Syntax

merge::=

**Note**

You must specify at least one of the clauses *merge_update_clause* or *merge_insert_clause*.

(values_clause::=, merge update clause::=, merge insert clause::=, wait_clause ,error logging clause::=, returning clause::=

values_clause::=**merge_update_clause::=****column_value_pairs::=****merge_insert_clause::=**

wait_clause**where_clause::=****error_logging_clause::=****returning_clause::=****Semantics****INTO Clause**

Use the INTO clause to specify the target table or view you are updating or inserting into. In order to merge data into a view, the view must be updatable. Refer to "[Notes on Updatable Views](#)" for more information.

Restriction on Target Views

You cannot specify a target view on which an INSTEAD OF trigger has been defined.

USING Clause

Use the USING clause to specify the source you are updating or inserting from.

values_clause

For semantics of the *values_clause* please see the *values_clause* of the SELECT statement [values_clause](#).

ON Clause

Use the ON clause to specify the condition upon which the MERGE operation either updates or inserts. For each row in the target table for which the search condition is true, the database updates the row with corresponding data from the source. If the condition is not true for any rows, then the database inserts into the target table based on the corresponding source row.

merge_update_clause

The *merge_update_clause* specifies the new column values of the target table or view. Oracle performs this update if the condition of the ON clause is true. If the update clause is executed, then all update triggers defined on the target table are activated.

Specify the *where_clause* if you want the database to execute the update operation only if the specified condition is true. The condition can refer to either the data source or the target table. If the condition is not true, then the database skips the update operation when merging the row into the table.

Specify the DELETE *where_clause* to clean up data in a table while populating or updating it. The only rows affected by this clause are those rows in the destination table that are updated by the merge operation. The DELETE WHERE condition evaluates the updated value, not the original value that was evaluated by the UPDATE SET ... WHERE condition. If a row of the destination table meets the DELETE condition but is not included in the join defined by the ON clause, then it is not deleted. Any delete triggers defined on the target table will be activated for each row deletion.

You can specify this clause by itself or with the *merge_insert_clause*. If you specify both, then they can be in either order.

Restrictions on the *merge_update_clause*

This clause is subject to the following restrictions:

- You cannot update a column that is referenced in the ON *condition* clause.
- You cannot specify DEFAULT when updating a view.
- You must specify *column_value_pairs* singly. No grouping allowed.

merge_insert_clause

The *merge_insert_clause* specifies values to insert into the column of the target table if the condition of the ON clause is false. If the insert clause is executed, then all insert triggers defined on the target table are activated. If you omit the column list after the INSERT keyword, then the number of columns in the target table must match the number of values in the VALUES clause.

To insert all of the source rows into the table, you can use a **constant filter predicate** in the ON clause condition. An example of a constant filter predicate is ON (0=1). the database recognizes such a predicate and makes an unconditional insert of all source rows into the table. This

approach is different from omitting the *merge_update_clause*. In that case, the database still must perform a join. With constant filter predicate, no join is performed.

Specify the *where_clause* if you want the database to execute the insert operation only if the specified condition is true. The condition can refer only to the data source columns. the database skips the insert operation for all rows for which the condition is not true.

You can specify the *merge_insert_clause* by itself or with the *merge_update_clause*. If you specify both, then they can be in either order.

Restriction on the *merge_insert_clause*

- You cannot specify DEFAULT when inserting into a view.
- You cannot use a subquery with *column_value_pairs*.

wait_clause

The NOWAIT and WAIT clauses let you tell the database how to proceed if a transaction attempts to lock a row that is locked by another transaction.

Specify NOWAIT to rollback the DML statement immediately, if a lock exists.

Specify WAIT to instruct the database to wait *integer* SECONDS , MILLISECONDS, or MICROSECONDS. Seconds is the default.

Specify WAIT FOREVER to instruct the database to retain its default behavior of waiting for row locks indefinitely.

If you specify neither WAIT nor NOWAIT, then the database waits until the row is available and then returns the results of the SELECT statement.

error_logging_clause

The *error_logging_clause* has the same behavior in a MERGE statement as in an INSERT statement. Refer to the INSERT statement [error_logging_clause](#) for more information.

["Inserting Into a Table with Error Logging: Example"](#)

Examples

Merging into a Table: Example

The following example uses the bonuses table in the sample schema oe with a default bonus of 100. It then inserts into the bonuses table all employees who made sales, based on the sales_rep_id column of the oe.orders table. Finally, the human resources manager decides that employees with a salary of \$8000 or less should receive a bonus. Those who have not made sales get a bonus of 1% of their salary. Those who already made sales get an increase in their bonus equal to 1% of their salary. The MERGE statement implements these changes in one step:

```
CREATE TABLE bonuses (employee_id NUMBER, bonus NUMBER DEFAULT 100);
INSERT INTO bonuses(employee_id)
  (SELECT e.employee_id FROM hr.employees e, oe.orders o
   WHERE e.employee_id = o.sales_rep_id
   GROUP BY e.employee_id);
```

```
SELECT * FROM bonuses ORDER BY employee_id;
```

EMPLOYEE_ID	BONUS
153	100
154	100
155	100
156	100
158	100
159	100
160	100
161	100
163	100

```
MERGE INTO bonuses D
  USING (SELECT employee_id, salary, department_id FROM hr.employees
        WHERE department_id = 80) S
  ON (D.employee_id = S.employee_id)
  WHEN MATCHED THEN UPDATE SET D.bonus = D.bonus + S.salary*.01
  DELETE WHERE (S.salary > 8000)
  WHEN NOT MATCHED THEN INSERT (D.employee_id, D.bonus)
  VALUES (S.employee_id, S.salary*.01)
  WHERE (S.salary <= 8000);
```

```
SELECT * FROM bonuses ORDER BY employee_id;
```

EMPLOYEE_ID	BONUS
153	180
154	175
155	170
159	180
160	175
161	170
164	72
165	68
166	64
167	62
171	74
172	73
173	61
179	62

Conditional Insert and Update: Example

The following example conditionally inserts and updates table data by using the MERGE statement.

The following statements create two tables named `people_source` and `people_target` and populate them with names:

```
CREATE TABLE people_source (
  person_id INTEGER NOT NULL PRIMARY KEY,
  first_name VARCHAR2(20) NOT NULL,
  last_name  VARCHAR2(20) NOT NULL,
  title     VARCHAR2(10) NOT NULL
);
```

```
CREATE TABLE people_target (
```

```

    person_id INTEGER NOT NULL PRIMARY KEY,
    first_name VARCHAR2(20) NOT NULL,
    last_name  VARCHAR2(20) NOT NULL,
    title      VARCHAR2(10) NOT NULL
);

INSERT INTO people_target VALUES (1, 'John', 'Smith', 'Mr');
INSERT INTO people_target VALUES (2, 'alice', 'jones', 'Mrs');
INSERT INTO people_source VALUES (2, 'Alice', 'Jones', 'Mrs. ');
INSERT INTO people_source VALUES (3, 'Jane', 'Doe', 'Miss');
INSERT INTO people_source VALUES (4, 'Dave', 'Brown', 'Mr');

COMMIT;

```

The following statement compares the contents of `people_target` and `people_source` by using the `person_id` column. The values in the `people_target` table are updated when there is a match in the `people_source` table:

```

MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name  = ps.last_name,
        pt.title      = ps.title;

```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
2	Alice	Jones	Mrs.

```
ROLLBACK;
```

This statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column. The values in the `people_target` table are updated only when there is no match in the `people_source` table:

```

MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN NOT MATCHED THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
    VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);

```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
2	alice	jones	Mrs
3	Jane	Doe	Miss
4	Dave	Brown	Mr

```
ROLLBACK;
```

The following statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column and conditionally inserts and updates data in the `people_target` table. For each matching row in the `people_source` table, the values in the `people_target` table are updated by using the values from the `people_source` table. Any unmatched rows from the `people_source` table are added to the `people_target` table:

```
MERGE INTO people_target pt
USING people_source ps
ON (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
  SET pt.first_name = ps.first_name,
      pt.last_name = ps.last_name,
      pt.title = ps.title
WHEN NOT MATCHED THEN INSERT
  (pt.person_id, pt.first_name, pt.last_name, pt.title)
  VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);
```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
2	Alice	Jones	Mrs.
3	Jane	Doe	Miss
4	Dave	Brown	Mr

```
ROLLBACK;
```

The following statement compares the `people_target` and `people_source` tables by using the `person_id` column. When the `person_id` matches, the corresponding rows in the `people_target` table are updated by using values from the `people_source` table. The `DELETE` clause removes all the values in `people_target` where title is 'Mrs.'. When the `person_id` does not match, the rows from the `people_source` table are added to the `people_target` table.

The WHERE clause ensures that only values that have title as 'Mr' are added to the people_target table:

```
MERGE INTO people_target pt
USING people_source ps
ON    (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title
    DELETE where pt.title = 'Mrs.'
WHEN NOT MATCHED THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
    VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title)
    WHERE ps.title = 'Mr';
```

The following statements display the contents of the people_target table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
4	Dave	Brown	Mr

```
ROLLBACK;
```

Dealing with Inputs from an Application

Usually applications have to check for the existence of a row first in order to decide whether to INSERT a new row, or UPDATE an already existing one. The MERGE statement eliminates the need for such a check by allowing the use of bind variables inside the USING statement as a source.

The following statements demonstrate the use of bind variables to insert a new row into the people_target table:

```
var person_id  NUMBER;
var first_name VARCHAR2(20);
var last_name  VARCHAR2(20);
var title      VARCHAR2(10);

exec :person_id := 3;
exec :first_name := 'Gerald';
exec :last_name  := 'Walker';
exec :title      := 'Mr';

MERGE INTO people_target
    ON (person_id = :person_id)
WHEN MATCHED THEN UPDATE
    SET first_name = :first_name,
        last_name  = :last_name,
```

```

        title = :title
    WHEN NOT MATCHED THEN INSERT
        (person_id, first_name, last_name, title)
        VALUES (:person_id, :first_name, :last_name, :title);

```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
2	alice	jones	Mrs
3	Gerald	Walker	Mr

```
ROLLBACK;
```

The following statements demonstrate the use of bind variables to update an already existing row in the `people_target`. Note that the `MERGE` statement is identical to the one just used to insert a new row:

```

var person_id NUMBER;
var first_name VARCHAR2(20);
var last_name  VARCHAR2(20);
var title      VARCHAR2(10);

exec :person_id := 2;
exec :first_name := 'Alice';
exec :last_name  := 'Jones';
exec :title      := 'Mrs';

MERGE INTO people_target
    ON (person_id = :person_id)
WHEN MATCHED THEN UPDATE
    SET first_name = :first_name,
        last_name  = :last_name,
        title      = :title
WHEN NOT MATCHED THEN INSERT
    (person_id, first_name, last_name, title)
    VALUES (:person_id, :first_name, :last_name, :title);

```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

PERSON_ID	FIRST_NAME	LAST_NAME	TITLE
1	John	Smith	Mr
2	Alice	Jones	Mrs

ROLLBACK;

Merge Using Wait: Example

Note: AUTOCOMMIT is OFF.

Fork 2 sessions and run the commands alternatively in each as follows:

Session 1:

```
MERGE INTO employees target USING employees_updates source
ON(target.employee_id = source.employee_id )
WHEN MATCHED THEN
  UPDATE SET
    target.first_name=source.first_name,
    target.last_name=source.last_name,
    target.salary=source.salary
WHEN NOT MATCHED THEN
  INSERT (employee_id, first_name, last_name, salary)
  VALUES ( source.employee_id, source.first_name, source.last_name,
source_salary);
```

3 rows merged.

Session 2:

```
MERGE INTO employees target USING employees_updates source
ON(target.employee_id = source.employee_id )
WHEN MATCHED THEN
  UPDATE SET
    target.first_name=source.first_name,
    target.last_name=source.last_name,
    target.salary=source.salary
WHEN NOT MATCHED THEN
  INSERT (employee_id, first_name, last_name, salary)
  VALUES ( source.employee_id, source.first_name, source.last_name,
source_salary)
  WAIT 10;
```

The statement fails after waiting 10 seconds. Error messages:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",
Description: "Lock held by a transaction to allow other transactions to wait
for it") because it is currently held by another session. The resource being
locked can be identified by 262148 ("usn<<16 | slot") and 1428 ("sequence")
ORA-40097: Failure to acquire row lock, currently held by transaction ID 4.4.1428
```

Session 1:

```
COMMIT;
Commit complete.
```

NOAUDIT (Traditional Auditing)

❶ See Also

Traditional auditing is desupported in 26ai. Databases migrated from earlier versions may still have traditional auditing policies configured. Those policies should be migrated to unified auditing. When migrated, the traditional audit policies may be removed with the NOAUDIT statement.

This section describes the NOAUDIT statement for **traditional auditing**, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces **unified auditing**, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be desupported in a future major release.

❶ See Also

[NOAUDIT \(Unified Auditing\)](#) for a description of the NOAUDIT statement for unified auditing

Purpose

Use the NOAUDIT statement to stop auditing operations previously enabled by the AUDIT statement.

The NOAUDIT statement must have the same syntax as the previous AUDIT statement. Further, it reverses the effects only of that particular statement. For example, suppose one AUDIT statement A enables auditing for a specific user. A second statement B enables auditing for all users. A NOAUDIT statement C to disable auditing for all users reverses statement B. However, statement C leaves statement A in effect and continues to audit the user that statement A specified.

Prerequisites

To stop auditing of SQL statements, you must have the AUDIT SYSTEM system privilege.

To stop auditing of schema objects, you must be the owner of the object on which you stop auditing or you must have the AUDIT ANY system privilege. In addition, if the object you chose for auditing is a directory, then even if you created it, you must have the AUDIT ANY system privilege.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege in order to stop auditing for the issuances of a SQL statement, or the commonly granted AUDIT ANY privilege in order to stop auditing for the operations on a schema object. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB) and you must have the locally granted AUDIT SYSTEM privilege in

order to stop auditing the issuances of a SQL statement, or the locally granted AUDIT ANY privilege in order to stop auditing operations on a schema object.

Syntax

noaudit::=

([audit_operation_clause::=](#), [auditing_by_clause::=](#), [audit_schema_object_clause::=](#))

audit_operation_clause::=

auditing_by_clause::=

audit_schema_object_clause::=

auditing_on_clause::=**Semantics*****audit_operation_clause***

Use the *audit_operation_clause* to stop auditing of a particular SQL statement.

statement_option

For *sql_statement_shortcut*, specify the shortcut for the SQL statements for which auditing is to be stopped.

ALL

Specify ALL to stop auditing of all statement options currently being audited because of an earlier AUDIT ALL . . . statement. You cannot use this clause to reverse an earlier AUDIT ALL STATEMENTS . . . statement.

ALL STATEMENTS

Specify ALL STATEMENTS to reverse an earlier AUDIT ALL STATEMENTS . . . statement. You cannot use this clause to reverse an earlier AUDIT ALL . . . statement.

system_privilege

For *system_privilege*, specify the system privilege for which auditing is to be stopped. Refer to [Table 18-2](#) for a list of the system privileges and the statements they authorize.

ALL PRIVILEGES

Specify ALL PRIVILEGES to stop auditing of all system privileges currently being audited.

auditing_by_clause

Use the *auditing_by_clause* to stop auditing only for SQL statements issued by the specified users in their subsequent sessions. If you omit this clause, then Oracle Database stops auditing for all users' statements, except for the situation described for WHENEVER SUCCESSFUL.

audit_schema_object_clause

Use the *audit_schema_object_clause* to stop auditing of a particular database object.

sql_operation

For *sql_operation*, specify the type of operation for which auditing is to be stopped on the object specified in the ON clause.

ALL

Specify ALL as a shortcut equivalent to specifying all SQL operations applicable for the type of object.

auditing_on_clause

The *auditing_on_clause* lets you specify the particular schema object for which auditing is to be stopped.

- For object, specify the object name of a table, view, sequence, stored procedure, function, or package, materialized view, or library. If you do not qualify *object* with *schema*, then Oracle Database assumes the object is in your own schema.
- The DIRECTORY clause lets you specify the name of the directory on which auditing is to be stopped.
- The SQL TRANSLATION PROFILE clause lets you specify the SQL translation profile on which auditing is to be stopped.
- Specify DEFAULT to remove the specified object options as default object options for subsequently created objects.

NETWORK

Use this clause to discontinue auditing of database link usage and logins.

DIRECT_PATH LOAD

Use this clause to discontinue auditing of SQL*Loader direct path loads.

WHENEVER [NOT] SUCCESSFUL

Specify WHENEVER SUCCESSFUL to stop auditing only for SQL statements and operations on schema objects that complete successfully.

Specify WHENEVER NOT SUCCESSFUL to stop auditing only for SQL statements and operations that result in Oracle Database errors.

If you omit this clause, then the database stops auditing for all statements or operations, regardless of success or failure.

CONTAINER Clause

Use the CONTAINER clause to specify the scope of the NOAUDIT command.

- Specify CONTAINER = CURRENT to stop auditing in the PDB to which you are connected. If you specify the *auditing_by_clause*, then *user* must be a common user or local user in the current PDB. If you specify the *auditing_on_clause*, then the objects must be local objects in the current PDB.
- Specify CONTAINER = ALL to stop auditing across the entire CDB. If you specify the *auditing_by_clause*, then *user* must be a common user. If you do not specify the *auditing_by_clause*, then auditing is stopped for all common users and all local users in each PDB. If you specify the *auditing_on_clause*, then the objects must be common objects.

If you omit this clause, then CONTAINER = CURRENT is the default.

Examples**Stop Auditing of SQL Statements Related to Roles: Example**

If you have chosen auditing for every SQL statement that creates or drops a role, then you can stop auditing of such statements by issuing the following statement:

```
NOAUDIT ROLE;
```

Stop Auditing of Updates or Queries on Objects Owned by a Particular User: Example

If you have chosen auditing for any statement that queries or updates any table issued by the users hr and oe, then you can stop auditing for queries by hr by issuing the following statement:

```
NOAUDIT SELECT TABLE BY hr;
```

The preceding statement stops auditing only queries by hr, so the database continues to audit queries and updates by oe as well as updates by hr.

Stop Auditing of Statements Authorized by a Particular Object Privilege: Example

To stop auditing on all statements that are authorized by DELETE ANY TABLE system privilege, issue the following statement:

```
NOAUDIT DELETE ANY TABLE;
```

Stop Auditing of Queries on a Particular Object: Example

If you have chosen auditing for every SQL statement that queries the employees table in the schema hr, then you can stop auditing for such queries by issuing the following statement:

```
NOAUDIT SELECT  
  ON hr.employees;
```

Stop Auditing of Queries that Complete Successfully: Example

You can stop auditing for queries that complete successfully by issuing the following statement:

```
NOAUDIT SELECT  
  ON hr.employees  
  WHENEVER SUCCESSFUL;
```

This statement stops auditing only for successful queries. Oracle Database continues to audit queries resulting in Oracle Database errors.

NOAUDIT (Unified Auditing)

This section describes the NOAUDIT statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

Purpose

Use the NOAUDIT statement to:

- Disable a unified audit policy for all users or for specified users
- Exclude the values of context attributes from audit records

Changes made to the audit policy become effective immediately in the current session and in all active sessions without re-login.

See Also

- [AUDIT \(Unified Auditing\)](#)
- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [DROP AUDIT POLICY \(Unified Auditing\)](#)

Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

If you are connected to a multitenant container database (CDB), then to disable a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To disable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container.

To specify the NOAUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the current session's container.

Syntax

unified_noaudit::=

by_users_with_roles::=

**Semantics*****policy***

Specify the name of the unified audit policy you want to disable.

You can find descriptions of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and descriptions of all *enabled* unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view.

① See Also

Oracle Database Reference for more information on the `AUDIT_UNIFIED_POLICIES` and `AUDIT_UNIFIED_ENABLED_POLICIES` views

CONTEXT Clause

Specify the `CONTEXT` clause to exclude the values of context attributes in audit records.

- For *namespace*, specify the context namespace.
- For *attribute*, specify one or more context attributes whose values you want to exclude from audit records.

If you specify the `CONTEXT` clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional `BY` clause, then *user* must be a common user.

If you specify the `CONTEXT` clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional `BY` clause, then *user* must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

① See Also

Oracle Database Reference for more information on the `AUDIT_UNIFIED_CONTEXTS` view

BY

You can specify the `BY` clause for the `NOAUDIT POLICY` and `NOAUDIT CONTEXT` statements.

NOAUDIT POLICY ... BY

The behavior of the `BY` clause depends on whether *policy* is enabled for all users or specific users.

- If *policy* is enabled for all users, then you can disable *policy* for all users by omitting the `BY` clause. If you specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.
- If *policy* is enabled for one or more users (using the `AUDIT POLICY ... BY ...` statement), then you can:
 - Disable *policy* for one or more of those users by specifying the `BY` clause followed by the users for whom you want *policy* disabled
 - Completely disable *policy* by specifying the `BY` clause followed by all of the users for whom *policy* is enabled

If you do not specify the BY clause, then the NOAUDIT POLICY statement will have no effect.

- If *policy* is enabled for all users except specific users (using the AUDIT POLICY ... EXCEPT ... statement), then you can disable *policy* for all users by omitting the BY clause. If you specify the BY clause, then the NOAUDIT POLICY statement will have no effect.

If *policy* is a common unified audit policy, then *user* must be a common user. If *policy* is a local unified audit policy, then *user* must be a common user or a local user in the container to which you are connected.

NOAUDIT CONTEXT ... BY

The behavior of the BY clause depends on whether *attribute* is configured to be included in audit records for all users or specific users.

- If *attribute* is configured to be included in audit records for all users, then you can exclude *attribute* from audit records for all users by omitting the BY clause. If you specify the BY clause, then the NOAUDIT CONTEXT statement will have no effect.
- If *attribute* is configured to be included in audit records for specific users, then you can exclude *attribute* for one or more of those users by specifying the BY clause followed by the users for whom you want *attribute* excluded. If you do not specify the BY clause, then the NOAUDIT CONTEXT statement will have no effect.

by_users_with_roles

Specify this clause to disable *policy* only for users who have been directly granted the specified roles. If you subsequently grant one of the roles to an additional user, then the policy is automatically disabled for that user.

When you are connected to a CDB, if *policy* is a common unified audit policy, then *role* must be a common role. If *policy* is a local unified audit policy, then *role* must be a common role or a local role in the container to which you are connected.

Examples

The following examples disable unified audit policies that were created in the CREATE AUDIT POLICY "[Examples](#)" and enabled in the AUDIT "[Examples](#)".

Disabling a Unified Audit Policy for All Users: Example

Assume that unified audit policy `table_pol` is enabled for all users. The following statement disables `table_pol` for all users:

```
NOAUDIT POLICY table_pol;
```

The following statement returns no rows, which verifies that `table_pol` is disabled for all users:

```
SELECT *  
FROM audit_unified_enabled_policies  
WHERE policy_name = 'TABLE_POL';
```

Disabling a Unified Audit Policy for Specific Users: Example

Assume that unified audit policy `dml_pol` is enabled for users `hr` and `sh`, as shown by the following query:

```
SELECT policy_name, enabled_option, entity_name  
FROM audit_unified_enabled_policies  
WHERE policy_name = 'DML_POL'  
ORDER BY entity_name;
```

POLICY_NAME	ENABLED_OPTION	ENTITY_NAME
-----	-----	-----
DML_POL	BY	HR
DML_POL	BY	SH

The following statement disables dml_pol for user hr:

```
NOAUDIT POLICY dml_pol BY hr;
```

The following statement verifies that dml_pol is now enabled for only user sh:

```
SELECT policy_name, enabled_option, entity_name
       FROM audit_unified_enabled_policies
       WHERE policy_name = 'DML_POL';
```

POLICY_NAME	ENABLED_OPTION	ENTITY_NAME
-----	-----	-----
DML_POL	BY	SH

The following statement disables dml_pol for user sh:

```
NOAUDIT POLICY dml_pol BY sh;
```

The following statement returns no rows, which verifies that dml_pol is disabled for all users:

```
SELECT *
       FROM audit_unified_enabled_policies
       WHERE policy_name = 'DML_POL';
```

Excluding Values of Context Attributes in Audit Records: Example

The following statement instructs the database to exclude the values of namespace USERENV attributes CURRENT_USER and DB_NAME from all audit records for user hr:

```
NOAUDIT CONTEXT NAMESPACE userenv
       ATTRIBUTES current_user, db_name
       BY hr;
```

PURGE

Purpose

Use the PURGE statement to:

- Remove a table or index from your recycle bin and release all of the space associated with the object
- Remove part or all of a dropped tablespace or tablespace set from the recycle bin
- Remove the entire recycle bin

Note

You cannot roll back a PURGE statement, nor can you recover an object after it is purged.

To see the contents of your recycle bin, query the USER_RECYCLEBIN data dictionary view. You can use the RECYCLEBIN synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

See Also

- *Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin
- [FLASHBACK TABLE](#) for information on retrieving dropped tables from the recycle bin
- *Oracle Database Reference* for information on using the RECYCLEBIN initialization parameter to control whether dropped tables go into the recycle bin

Prerequisites

To purge a table, the table must reside in your own schema or you must have the DROP ANY TABLE system privilege, or you must have the SYSDBA system privilege.

To purge an index, the index must reside in your own schema or you must have the DROP ANY INDEX system privilege, or you must have the SYSDBA system privilege.

To purge a tablespace or tablespace set, you must have the DROP TABLESPACE system privilege, or you must have the SYSDBA system privilege.

To purge a tablespace set, you must also be connected to a shard catalog database as an SDB user.

To perform the PURGE DBA_RECYCLEBIN operation, you must have the SYSDBA or PURGE DBA_RECYCLEBIN system privilege.

Syntax

purge::=

Semantics

TABLE or INDEX

Specify the name of the table or index in the recycle bin that you want to purge. You can specify either the original user-specified name or the system-generated name Oracle Database assigned to the object when it was dropped.

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database purges the object that has been in the recycle bin the longest.
- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database purges that specified object.

When the database purges a table, all table partitions, LOBs and LOB partitions, indexes, and other dependent objects of that table are also purged.

TABSPACE or TABLESPACE SET

Use this clause to purge all the objects residing in the specified tablespace or tablespace set from the recycle bin.

USER *user*

Use this clause to reclaim space in a tablespace or tablespace set for a specified user. This operation is useful when a particular user is running low on disk quota for the specified tablespace or tablespace set.

RECYCLEBIN

Use this clause to purge the current user's recycle bin. Oracle Database will remove all objects from the user's recycle bin and release all space associated with objects in the recycle bin.

DBA_RECYCLEBIN

This clause is valid only if you have the SYSDBA or PURGE DBA_RECYCLEBIN system privilege. It lets you remove all objects from the system-wide recycle bin, and is equivalent to purging the recycle bin of every user. This operation is useful, for example, before backward migration.

Examples

Remove a File From Your Recycle Bin: Example

The following statement removes the table `test` from the recycle bin. If more than one version of `test` resides in the recycle bin, then Oracle Database removes the version that has been there the longest:

```
PURGE TABLE test;
```

To determine system-generated name of the table you want removed from your recycle bin, issue a `SELECT` statement on your recycle bin. Using that object name, you can remove the table by issuing a statement similar to the following statement. (The system-generated name will differ from the one shown in the example.)

```
PURGE TABLE RB$$$33750$TABLE$0;
```

Remove the Contents of Your Recycle Bin: Example

To remove the entire contents of your recycle bin, issue the following statement:

```
PURGE RECYCLEBIN;
```

RENAME

Purpose

Note

You cannot roll back a RENAME statement.

Use the RENAME statement to rename a table, view, sequence, private synonym, or property graph.

- The database automatically transfers integrity constraints, indexes, and grants on the old object to the new object.
- The database invalidates all objects that depend on the renamed object, such as views, synonyms, and stored procedures and functions that refer to a renamed table.

See Also

[CREATE SYNONYM](#) and [DROP SYNONYM](#)

Prerequisites

The object must be in your own schema.

Syntax

rename::=

→ **RENAME** → *old_name* → **TO** → *new_name* → ;

Semantics

old_name

Specify the name of an existing table, view, sequence, or private synonym.

new_name

Specify the new name to be given to the existing object. The new name must not already be used by another schema object in the same namespace and must follow the rules for naming schema objects.

Restrictions on Renaming Objects

Renaming objects is subject to the following restrictions:

- You cannot rename a public synonym. Instead, drop the public synonym and then re-create the public synonym with the new name.

- You cannot rename a type synonym that has any dependent tables or dependent valid user-defined object types.
- You cannot rename a table that is used in a SQL assertion.

① See Also

["Database Object Naming Rules."](#)

Examples

Renaming a Database Object: Example

The following example uses a copy of the sample table `hr.departments`. To change the name of table `departments_new` to `emp_departments`, issue the following statement:

```
RENAME departments_new TO emp_departments;
```

You cannot use this statement directly to rename columns. However, you can rename a column using the `ALTER TABLE ... rename_column_clause`.

① See Also

[rename_column_clause](#)

Another way to rename a column is to use the `RENAME` statement together with the `CREATE TABLE` statement with `AS subquery`. This method is useful if you are changing the structure of a table rather than only renaming a column. The following statements re-create the sample table `hr.job_history`, renaming a column from `department_id` to `dept_id`:

```
CREATE TABLE temporary
  (employee_id, start_date, end_date, job_id, dept_id)
AS SELECT
  employee_id, start_date, end_date, job_id, department_id
FROM job_history;
```

```
DROP TABLE job_history;
```

```
RENAME temporary TO job_history;
```

Any integrity constraints defined on table `job_history` will be lost in the preceding example. You will have to redefine them on the new `job_history` table using an `ALTER TABLE` statement.

REVOKE

Purpose

Use the `REVOKE` statement to:

- Revoke system privileges from users and roles
- Revoke roles from users, roles, and program units.
- Revoke object privileges for a particular object from users and roles

- Revoke schema privileges from users and roles

Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to revoke the system privileges SYSASM, SYSOPER, and SYSDBA from a user in the Oracle ASM password file of the current node.

Note on Editionable Objects

A REVOKE operation to revoke object privileges on an editionable object actualizes the object in the current edition. See *Oracle Database Development Guide* for more information about editions and editionable objects.

① See Also

- [GRANT](#) for information on granting system privileges and roles
- [Table 18-4](#) for a listing of the object privileges for each type of object

Prerequisites

To revoke a **system privilege**, you must have been granted the privilege with the ADMIN OPTION. You can revoke any privilege if you have the GRANT ANY PRIVILEGE system privilege.

To revoke a **role from a user or another role**, you must have been directly granted the role with the ADMIN OPTION or you must have created the role. You can revoke any role if you have the GRANT ANY ROLE system privilege.

To revoke a **role from a program unit**, you must be the user SYS or you must be the schema owner of the program unit.

To revoke an **object privilege**, one of the following conditions must be met:

- You must previously have granted the object privilege to the user or role.
- You must have the GRANT ANY OBJECT PRIVILEGE system privilege.
- You must have the GRANT ANY OBJECT PRIVILEGE system privilege. In this case, you can revoke any object privilege that was granted by the object owner or on behalf of the owner by a user with the GRANT ANY OBJECT PRIVILEGE. However, you cannot revoke an object privilege that was granted by way of a WITH GRANT OPTION grant.
- You can revoke privileges on an object if you have the GRANT ANY object privilege. This does not apply to SYS objects. The ANY keyword in reference to a system privilege means that the user can perform the privilege on any objects owned by any user except for SYS.

① See Also

["Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example"](#)

The REVOKE statement can revoke only privileges and roles that were previously granted directly with a GRANT statement. You cannot use this statement to revoke:

- Privileges or roles not granted to the revokee
- Roles or object privileges granted through the operating system
- Privileges or roles granted to the revokee through roles

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root.

Syntax

revoke::=

[*\(revoke_system_privileges::=, revoke_object_privileges::=, revoke_roles_from_programs::=\)*](#)

revoke_system_privileges::=

[*\(revokee_clause::=\)*](#)

revoke_schema_privileges::=

[*\(revokee_clause::=\)*](#)

revoke_object_privileges::=

(*on_object_clause::=*, *revokee_clause::=*)

revokee_clause::=

on_object_clause::=

revoke_roles_from_programs::=

program_unit::=

Semantics

revoke_system_privileges

Use these clauses to revoke system privileges.

system_privilege

Specify the system privilege to be revoked. Refer to [Table 18-2](#) for a list of the system privileges.

If you revoke a system privilege from a **user**, then the database removes the privilege from the user's privilege domain. Effective immediately, the user cannot exercise the privilege.

If you revoke a system privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Also, other users who have been granted the role and subsequently enable the role cannot exercise the privilege.

① See Also

["Revoking a System Privilege from a User: Example"](#) and ["Revoking a System Privilege from a Role: Example"](#)

If you revoke a system privilege from **PUBLIC**, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, such users can no longer exercise the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

Oracle Database provides a shortcut for specifying all system privileges at once: Specify ALL PRIVILEGES to revoke all the system privileges listed in [Table 18-2](#).

Restriction on Revoking System Privileges

A system privilege cannot appear more than once in the list of privileges to be revoked.

role

Specify the role to be revoked.

If you revoke a role from a **user**, then the database makes the role unavailable to the user. If the role is currently enabled for the user, then the user can continue to exercise the privileges in the role's privilege domain as long as it remains enabled. However, the user cannot subsequently enable the role.

If you revoke a role from another **role**, then the database removes the privilege domain of the revoked role from the privilege domain of the revokee role. Users who have been granted and have enabled the revokee role can continue to exercise the privileges in the privilege domain of the revoked role as long as the revokee role remains enabled. However, other users who have been granted the revokee role and subsequently enable it cannot exercise the privileges in the privilege domain of the revoked role.

① See Also

["Revoking a Role from a User: Example"](#) and ["Revoking a Role from a Role: Example"](#)

If you revoke a role from **PUBLIC**, then the database makes the role unavailable to all users who have been granted the role through **PUBLIC**. Any user who has enabled the role can continue to exercise the privileges in its privilege domain as long as it remains enabled. However, users cannot subsequently enable the role. The role is not revoked from users who have been granted the role directly or through other roles.

Restriction on Revoking System Roles

A system role cannot appear more than once in the list of roles to be revoked. For information on the predefined roles, refer to *Oracle Database Security Guide*.

revokee_clause

Use the *revokee_clause* to specify the users or roles from which the system privilege, role, or object privilege is to be revoked.

PUBLIC

Specify **PUBLIC** to revoke the privileges or roles from all users.

revoke_schema_privileges

Use this clause to revoke schema privileges. You can revoke a schema level privilege from any user or any role if you are a user who :

- Owns the schema.
- Has a schema level privilege **WITH ADMIN OPTION**.
- Has the **GRANT ANY SCHEMA PRIVILEGE** system privilege. If you specify **ALL PRIVILEGES** , all the schema level privileges in [Table 18-3](#) are revoked.

revoke_object_privileges

Use these clauses to revoke object privileges.

object_privilege

Specify the object privilege to be revoked. The object privileges, categorized by the type of object to which they apply, are described in [Table 18-4](#).

Note

Each privilege authorizes some operation. By revoking a privilege, you prevent the revokee from performing that operation. However, multiple users may grant the same privilege to the same user, role, or **PUBLIC**. To remove the privilege from the grantee's privilege domain, all grantors must revoke the privilege. If even one grantor does not revoke the privilege, then the grantee can still exercise the privilege by virtue of that grant.

If you revoke an object privilege from a **user**, then the database removes the privilege from the user's privilege domain. Effective immediately, the user cannot exercise the privilege.

If you revoke an object privilege from a user who has existing column level privileges granted , then those column level privileges will also be revoked.

- If that user has granted that privilege to other users or roles, then the database also revokes the privilege from those other users or roles.

- If that user's schema contains a procedure, function, or package that contains SQL statements that exercise the privilege, then the procedure, function, or package can no longer be executed.
- If that user's schema contains a view on that object, then the database invalidates the view.
- If you revoke the REFERENCES object privilege from a user who has exercised the privilege to define referential integrity constraints, then you must specify the CASCADE CONSTRAINTS clause.
- If you revoke the ASSERTION REFERENCES object privilege from a user who has exercised the privilege to define SQL assertions, then you must specify the CASCADE CONSTRAINTS clause.

If you revoke an object privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Other users who have been granted the role cannot exercise the privilege after enabling the role.

If you revoke an object privilege from PUBLIC, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, all such users are restricted from exercising the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

ALL [PRIVILEGES]

Specify ALL to revoke all object privileges that you have granted to the revokee. (The keyword PRIVILEGES is provided for semantic clarity and is optional.)

If no privileges have been granted on the object, then the database takes no action and does not return an error.

Restriction on Revoking Object Privileges

A privilege cannot appear more than once in the list of privileges to be revoked. A user, a role, or PUBLIC cannot appear more than once in the FROM clause.

① See Also

["Revoking an Object Privilege from a User: Example"](#), ["Revoking Object Privileges from PUBLIC: Example"](#), and ["Revoking All Object Privileges from a User: Example"](#)

CASCADE CONSTRAINTS

This clause is relevant only if you revoke the (ASSERTIONS)REFERENCES privilege or ALL [PRIVILEGES]. It drops any referential integrity constraints or SQL assertions that the revokee has defined using the (ASSERTIONS)REFERENCES privilege.

① See Also

["Revoking an Object Privilege with CASCADE CONSTRAINTS: Example"](#)

FORCE

Specify **FORCE** to revoke the **EXECUTE** object privilege on user-defined type objects with table or type dependencies. You must use **FORCE** to revoke the **EXECUTE** object privilege on user-defined type objects with table dependencies.

If you specify **FORCE**, then all privileges are revoked, all dependent objects are marked **INVALID**, data in dependent tables becomes inaccessible, and all dependent function-based indexes are marked **UNUSABLE**. Regranting the necessary type privilege will revalidate the table.

📘 See Also

Oracle Database Concepts for detailed information about type dependencies and user-defined object privileges

on_object_clause

The *on_object_clause* identifies the objects on which privileges are to be revoked.

object

Specify the object on which the object privileges are to be revoked. This object can be:

- A table, view, sequence, procedure, stored function, package, or materialized view
- A synonym for a table, view, sequence, procedure, stored function, package, materialized view, or user-defined type
- A library, indextype, or user-defined operator

If you do not qualify object with *schema*, then the database assumes the object is in your own schema.

📘 See Also

["Revoking an Object Privilege on a Sequence from a User: Example"](#)

If you revoke the **READ** or **SELECT** object privilege on the containing table or materialized view of a materialized view, whether the privilege was granted with or without the **GRANT OPTION**, then the database invalidates the materialized view.

If you revoke the **READ** or **SELECT** object privilege on any of the master tables of a materialized view, whether the privilege was granted with or without the **GRANT OPTION**, then the database invalidates both the materialized view and its containing table or materialized view.

ON USER

Specify the database user you want to revoke privileges from.

📘 See Also

["Revoking an Object Privilege on a User from a User: Example"](#)

ON DIRECTORY

Specify the name of the directory object on which privileges are to be revoked. You cannot qualify *directory_name* with a schema name.

① See Also

[CREATE DIRECTORY](#) and "[Revoking an Object Privilege on a Directory from a User: Example](#)"

ON EDITION

Specify the name of the edition on which the USE object privilege is to be revoked. You cannot qualify *edition_name* with a schema name.

ON MINING MODEL

Specify the name of the mining model on which privileges are to be revoked. If you do not qualify *mining_model_name* with *schema*, then the database assumes that the mining model is in your own schema.

ON JAVA SOURCE | RESOURCE

Specify the name of the Java source or resource schema object on which privileges are to be revoked. If you do not qualify *object* with *schema*, then the database assumes that the object is in your own schema.

ON SQL TRANSLATION PROFILE

Specify the name of the SQL translation profile on which privileges are to be revoked. If you do not qualify *profile* with *schema*, then the database assumes the profile is in your own schema.

revoke_roles_from_programs

Use this clause to revoke code based access control (CBAC) roles from program units.

role

Specify the role you want to revoke.

ALL

Specify ALL to revoke all roles that are granted to the program unit.

program_unit

Specify the program unit from which the role is to be revoked. You can specify a PL/SQL function, procedure, or package. If you do not specify *schema*, then Oracle Database assumes the function, procedure, or package is in your own schema.

① See Also

Oracle Database Security Guide for more information on revoking CBAC roles from program units

CONTAINER Clause

If the current container is a pluggable database (PDB):

- Specify `CONTAINER = CURRENT` to revoke a locally granted system privilege, object privilege, or role from a local user, common user, local role, or common role. The privilege or role is revoked from the user or role only in the current PDB. This clause does not revoke privileges granted with `CONTAINER = ALL`.

If the current container is the root:

- Specify `CONTAINER = CURRENT` to revoke a locally granted system privilege, object privilege, or role from a common user or common role. The privilege or role is revoked from the user or role only in the root. This clause does not revoke privileges granted with `CONTAINER = ALL`.
- Specify `CONTAINER = ALL` to revoke a commonly granted system privilege, object privilege on a common object, or role from a common user or common role. The privilege or role is revoked from the user or role across the entire CDB. This clause can revoke only a privilege or role granted with `CONTAINER = ALL` from the specified common user or common role. This clause does not revoke privileges granted locally with `CONTAINER = CURRENT`. However, any locally granted privileges that depend on the commonly granted privilege being revoked are also revoked.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

Examples

Revoking a System Privilege from a User: Example

The following statement revokes the `DROP ANY TABLE` system privilege from the users `hr` and `oe`:

```
REVOKE DROP ANY TABLE
FROM hr, oe;
```

The users `hr` and `oe` can no longer drop tables in schemas other than their own.

Revoking a Role from a User: Example

The following statement revokes the role `dw_manager` from the user `sh`:

```
REVOKE dw_manager
FROM sh;
```

The user `sh` can no longer enable the `dw_manager` role.

Revoking a System Privilege from a Role: Example

The following statement revokes the `CREATE TABLESPACE` system privilege from the `dw_manager` role:

```
REVOKE CREATE TABLESPACE
FROM dw_manager;
```

Enabling the `dw_manager` role no longer allows users to create tablespaces.

Revoking a Role from a Role: Example

To revoke the role `dw_user` from the role `dw_manager`, issue the following statement:

```
REVOKE dw_user
FROM dw_manager;
```

The `dw_user` role privileges are no longer granted to `dw_manager`.

Revoking an Object Privilege from a User: Example

You can grant DELETE, INSERT, READ, SELECT, and UPDATE privileges on the table orders to the user hr with the following statement:

```
GRANT ALL
    ON orders TO hr;
```

To revoke the DELETE privilege on orders from hr, issue the following statement:

```
REVOKE DELETE
    ON orders FROM hr;
```

Revoking All Object Privileges from a User: Example

To revoke the remaining privileges on orders that you granted to hr, issue the following statement:

```
REVOKE ALL
    ON orders FROM hr;
```

Revoking Object Privileges from PUBLIC: Example

You can grant SELECT and UPDATE privileges on the view emp_details_view to all users by granting the privileges to the role PUBLIC:

```
GRANT SELECT, UPDATE
    ON emp_details_view TO public;
```

The following statement revokes UPDATE privilege on emp_details_view from all users:

```
REVOKE UPDATE
    ON emp_details_view FROM public;
```

Users can no longer update the emp_details_view view, although users can still query it. However, if you have also granted the UPDATE privilege on emp_details_view to any users, either directly or through roles, then these users retain the privilege.

Revoking an Object Privilege on a User from a User: Example

You can grant the user hr the INHERIT PRIVILEGES privilege on user sh with the following statement:

```
GRANT INHERIT PRIVILEGES ON USER sh TO hr;
```

To revoke the INHERIT PRIVILEGES privilege on user sh from user hr, issue the following statement:

```
REVOKE INHERIT PRIVILEGES ON USER sh FROM hr;
```

Revoking an Object Privilege on a Sequence from a User: Example

You can grant the user oe the SELECT privilege on the departments_seq sequence in the schema hr with the following statement:

```
GRANT SELECT
    ON hr.departments_seq TO oe;
```

To revoke the SELECT privilege on departments_seq from oe, issue the following statement:

```
REVOKE SELECT
    ON hr.departments_seq FROM oe;
```

However, if the user hr has also granted SELECT privilege on departments to sh, then sh can still use departments by virtue of hr's grant.

Revoking an Object Privilege with CASCADE CONSTRAINTS: Example

You can grant to oe the privileges REFERENCES and UPDATE on the employees table in the schema hr with the following statement:

```
GRANT REFERENCES, UPDATE
  ON hr.employees TO oe;
```

The user oe can exercise the REFERENCES privilege to define a constraint in his or her own dependent table that refers to the employees table in the schema hr:

```
CREATE TABLE dependent
(dependno    NUMBER,
 dependname VARCHAR2(10),
 employee    NUMBER
  CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

You can revoke the REFERENCES privilege on hr.employees from oe by issuing the following statement that contains the CASCADE CONSTRAINTS clause:

```
REVOKE REFERENCES
  ON hr.employees
  FROM oe
  CASCADE CONSTRAINTS;
```

Revoking oe's REFERENCES privilege on hr.employees causes Oracle Database to drop the in_emp constraint, because oe required the privilege to define the constraint.

However, if oe has also been granted the REFERENCES privilege on hr.employees by a user other than you, then the database does not drop the constraint. oe still has the privilege necessary for the constraint by virtue of the other user's grant.

Revoking an Object Privilege on a Directory from a User: Example

You can revoke the READ object privilege on directory bfile_dir from hr by issuing the following statement:

```
REVOKE READ ON DIRECTORY bfile_dir FROM hr;
```

Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example

Suppose that the database administrator has granted GRANT ANY OBJECT PRIVILEGE to user sh. Now suppose that user hr grants the update privilege on the employees table to oe:

```
CONNECT hr
GRANT UPDATE ON employees TO oe WITH GRANT OPTION;
```

This grant gives user oe the right to pass the object privilege along to another user:

```
CONNECT oe
GRANT UPDATE ON hr.employees TO pm;
```

User sh, who has the GRANT ANY OBJECT PRIVILEGE, can now act on behalf of user hr and revoke the update privilege from user oe, because oe was granted the privilege by hr:

```
CONNECT sh
REVOKE UPDATE ON hr.employees FROM oe;
```

User sh cannot revoke the update privilege from user pm explicitly, because pm received the grant neither from the object owner (hr), nor from sh, nor from another user with GRANT ANY OBJECT PRIVILEGE, but from user oe. However, the preceding statement cascades, removing all

privileges that depend on the one revoked. Therefore the object privilege is implicitly revoked from pm as well.

REVOKE DATA ROLE

Purpose

Use REVOKE DATA ROLE to revoke data roles from grantees.

Prerequisites

You must have the GRANT ANY DATA ROLE system privilege to execute this command.

You can use the DBA_DATA_ROLE_GRANTS dictionary view to query existing data role grants.

Syntax

***revokee_list*::=**

***revokee*::=**

Semantics

- **IF EXISTS:** If you specify IF EXISTS and the data role does not exist, no error is thrown. If the data role exists, then it will be revoked.

If you do not specify IF EXISTS, and the data role does not exist, an error is thrown. If the data role exists, then it will be revoked.

- **data_role_list:** the names of data roles to be revoked.
- **revokee_list:** the names of the end users, application identities, or data roles from which data roles need to be revoked.

Example

The following SQL statement revokes the data role manager_role from the end user marvin:

```
REVOKE DATA ROLE manager_role FROM marvin;
```

ROLLBACK

Purpose

Use the ROLLBACK statement to undo work done in the current transaction or to manually undo the work done by an in-doubt distributed transaction.

Note

Oracle recommends that you explicitly end transactions in application programs using either a COMMIT or ROLLBACK statement. If you do not explicitly commit the transaction and the program terminates abnormally, then Oracle Database rolls back the last uncommitted transaction.

See Also

- *Oracle Database Concepts* for information on transactions
- *Oracle Database Heterogeneous Connectivity User's Guide* for information on distributed transactions
- [SET TRANSACTION](#) for information on setting characteristics of the current transaction
- [COMMIT](#) and [SAVEPOINT](#)

Prerequisites

To roll back your current transaction, no privileges are necessary.

To manually roll back an in-doubt distributed transaction that you originally committed, you must have the FORCE TRANSACTION system privilege. To manually roll back an in-doubt distributed transaction originally committed by another user, you must have the FORCE ANY TRANSACTION system privilege.

Syntax

rollback::=

Semantics

WORK

The keyword WORK is optional and is provided for SQL standard compatibility.

TO SAVEPOINT Clause

Specify the savepoint to which you want to roll back the current transaction. If you omit this clause, then the ROLLBACK statement rolls back the entire transaction.

Using ROLLBACK without the TO SAVEPOINT clause performs the following operations:

- Ends the transaction
- Undoes all changes in the current transaction
- Erases all savepoints in the transaction
- Releases any transaction locks

 **See Also**
[SAVEPOINT](#)

Using ROLLBACK with the TO SAVEPOINT clause performs the following operations:

- Rolls back just the portion of the transaction after the savepoint. It does not end the transaction.
- Erases all savepoints created after that savepoint. The named savepoint is retained, so you can roll back to the same savepoint multiple times. Prior savepoints are also retained.
- Releases all table and row locks acquired since the savepoint. Other transactions that have requested access to rows locked after the savepoint must continue to wait until the transaction is committed or rolled back. Other transactions that have not already requested the rows can request and access the rows immediately.

Restriction on In-doubt Transactions

You cannot manually roll back an in-doubt transaction to a savepoint.

FORCE Clause

Specify FORCE to manually roll back an in-doubt distributed transaction. The transaction is identified by the *string* containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view DBA_2PC_PENDING.

A ROLLBACK statement with a FORCE clause rolls back only the specified transaction. Such a statement does not affect your current transaction.

 **See Also**

Oracle Database Administrator's Guide for more information on distributed transactions and rolling back in-doubt transactions

Examples

Rolling Back Transactions: Examples

The following statement rolls back your entire current transaction:

```
ROLLBACK;
```

The following statement rolls back your current transaction to savepoint `banda_sal`:

```
ROLLBACK TO SAVEPOINT banda_sal;
```

See "[Creating Savepoints: Example](#)" for a full version of the preceding example.

The following statement manually rolls back an in-doubt distributed transaction:

```
ROLLBACK WORK  
FORCE '25.32.87';
```

SAVEPOINT

Purpose

Use the `SAVEPOINT` statement to create a name for a system change number (SCN), to which you can later roll back.

See Also

- *Oracle Database Concepts* for information on savepoints.
- [ROLLBACK](#) for information on rolling back transactions
- [SET TRANSACTION](#) for information on setting characteristics of the current transaction

Prerequisites

None.

Syntax

savepoint::=

→ `SAVEPOINT` → `savepoint` → `;`

Semantics

savepoint

Specify the name of the savepoint to be created.

Savepoint names must be distinct within a given transaction. If you create a second savepoint with the same identifier as an earlier savepoint, then the earlier savepoint is erased. After a savepoint has been created, you can either continue processing, commit your work, roll back the entire transaction, or roll back to the savepoint.

Examples

Creating Savepoints: Example

To update the salary for Banda and Greene in the sample table `hr.employees`, check that the total department salary does not exceed 314,000, then reenter the salary for Greene:

```
UPDATE employees
  SET salary = 7000
  WHERE last_name = 'Banda';
SAVEPOINT banda_sal;

UPDATE employees
  SET salary = 12000
  WHERE last_name = 'Greene';
SAVEPOINT greene_sal;

SELECT SUM(salary) FROM employees;

ROLLBACK TO SAVEPOINT banda_sal;

UPDATE employees
  SET salary = 11000
  WHERE last_name = 'Greene';

COMMIT;
```

SELECT

Purpose

Use a SELECT statement or subquery to retrieve data from one or more tables, object tables, views, object views, materialized views, analytic views, or hierarchies.

If part or all of the result of a SELECT statement is equivalent to an existing materialized view, then the database may use the materialized view in place of one or more tables specified in the SELECT statement. This substitution is called **query rewrite**. It takes place only if cost optimization is enabled and the QUERY_REWRITE_ENABLED parameter is set to TRUE. To determine whether query rewrite has occurred, use the EXPLAIN PLAN statement.

See Also

- [SQL Queries and Subqueries](#) for general information on queries and subqueries
- *Oracle AI Database Data Warehousing Guide* materialized views, *Oracle AI Database Data Warehousing Guide* query rewrite, and analytic views and hierarchies
- If you are querying JSON data see *Query JSON Data*
- If you are querying XML data see *Querying XML Content Stored in Oracle XML DB*
- [EXPLAIN PLAN](#)

Prerequisites

For you to select data from a table, materialized view, analytic view, or hierarchy, the object must be in your own schema or you must have the READ or SELECT privilege on the table, materialized view, analytic view, or hierarchy.

For you to select rows from the base tables of a view:

- The object must be in your own schema or you must have the READ or SELECT privilege on it, and

- Whoever owns the schema containing the object must have the READ or SELECT privilege on the base tables.

The READ ANY TABLE or SELECT ANY TABLE system privilege also allows you to select data from any table, materialized view, analytic view, or hierarchy, or the base table of any materialized view, analytic view, or hierarchy.

To specify the FOR UPDATE clause, the preceding prerequisites apply with the following exception: The READ and READ ANY TABLE privileges, where mentioned, do not allow you to specify the FOR UPDATE clause.

To issue an Oracle Flashback Query using the *flashback_query_clause*, you must have the READ or SELECT privilege on the objects in the select list. In addition, either you must have FLASHBACK object privilege on the objects in the select list, or you must have FLASHBACK ANY TABLE system privilege.

Syntax

Semantics

with_clause

Use the *with_clause* to define the following:

- PL/SQL procedures and functions (using the *plsql_declarations* clause)
- Subquery blocks (using *subquery_factoring_clause* or *subav_factoring_clause*, or both)

You can nest correlated and non-correlated *with_clause* in SELECT.

The following clauses are unsupported with nested *with_clause*:

- Recursive WITH clauses nested inside another WITH clause
- Nested WITH clauses within a recursive WITH clause
- Defining a PL/SQL function inside a nested WITH clause
- Using table value constructors within a nested WITH clause

You cannot specify *with_clause* after set the operators (UNION, INTERSECT, EXCEPT, MINUS).

plsql_declarations

The *plsql_declarations* clause lets you declare and define PL/SQL functions and procedures. You can then reference the PL/SQL functions in the query in which you specify this clause, as well as its subqueries, if any. For the purposes of name resolution, these function names have precedence over schema-level stored functions.

If the query in which you specify this clause is not a top-level SELECT statement, then the following rules apply to the top-level SQL statement that contains the query:

- If the top-level statement is a SELECT statement, then it must have either a WITH *plsql_declarations* clause or the WITH_PLSQL hint.
- If the top-level statement is a DELETE, MERGE, INSERT, or UPDATE statement, then it must have the WITH_PLSQL hint.

The WITH_PLSQL hint only enables you to specify the WITH *plsql_declarations* clause within the statement. It is not an optimizer hint.

① See Also

- *Oracle AI Database PL/SQL Language Reference* *function_declaration* and *procedure_declaration* for syntax and restrictions.
- ["Using a PL/SQL Function in the WITH Clause: Examples"](#)

subquery_factoring_clause

The *subquery_factoring_clause* lets you assign a name (*query_name*) to a subquery block. You can then reference the subquery block multiple places in the query by specifying *query_name*. The database optimizes the query by treating the *query_name* as either an inline view or as a temporary table. The *query_name* is subject to the same naming conventions and restrictions as database schema objects. Refer to "[Database Object Naming Rules](#)" for information on database object names.

The column aliases following the *query_name* and the set operators separating multiple subqueries in the AS clause are valid and required for recursive subquery factoring. The *search_clause* and *cycle_clause* are valid only for recursive subquery factoring but are not required. See "[Recursive Subquery Factoring](#)".

You can specify this clause in any top-level SELECT statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries. For recursive subquery factoring, the query name is even visible to the subquery that defines the query name itself.

Recursive Subquery Factoring

If a *subquery_factoring_clause* refers to its own *query_name* in the subquery that defines it, then the *subquery_factoring_clause* is said to be **recursive**. A recursive *subquery_factoring_clause* must contain two query blocks: the first is the **anchor member** and the second is the **recursive member**. The anchor member must appear before the recursive member, and it cannot reference *query_name*. The anchor member can be composed of one or more query blocks combined by the set operators: UNION ALL, UNION, INTERSECT or MINUS. The recursive member must follow the anchor member and must reference *query_name* exactly once. You must combine the recursive member with the anchor member using the UNION ALL set operator.

The number of column aliases following WITH *query_name* and the number of columns in the SELECT lists of the anchor and recursive query blocks must be the same.

The recursive member cannot contain any of the following elements:

- The DISTINCT keyword or a GROUP BY clause
- The *model_clause*
- An aggregate function. However, analytic functions are permitted in the select list.
- Subqueries that refer to *query_name*.
- Outer joins that refer to *query_name* as the right table.

In previous releases of the database, the recursive member of a recursive WITH clause ran serially regardless of the parallelism of the entire query (also known as the top-level SELECT statement). Beginning with Release 12c Release 2 (12.2), the recursive member runs in parallel if the optimizer determines that the top-level SELECT statement can be executed in parallel.

search_clause

Use the SEARCH clause to specify an ordering for the rows.

- Specify BREADTH FIRST BY if you want sibling rows returned before any child rows are returned.
- Specify DEPTH FIRST BY if you want child rows returned before any siblings rows are returned.
- Sibling rows are ordered by the columns listed after the BY keyword.
- The *c_alias* list following the SEARCH keyword must contain column names from the column alias list for *query_name*.
- The *ordering_column* is automatically added to the column list for the query name. The query that selects from *query_name* can include an ORDER BY on *ordering_column* to return the rows in the order that was specified by the SEARCH clause.

cycle_clause

Use the CYCLE clause to mark cycles in the recursion.

- The *c_alias* list following the CYCLE keyword must contain column names from the column alias list for *query_name*. The database uses these columns to detect a cycle.
- *cycle_value* and *no_cycle_value* should be character strings of length 1.
- If a cycle is detected, then the cycle mark column specified by *cycle_mark_c_alias* for the row causing the cycle is set to the value specified for *cycle_value*. The recursion will then stop for this row. That is, it will not look for child rows for the offending row, but it will continue for other noncyclic rows.
- If no cycles are found, then the cycle mark column is set to the default value specified for *no_cycle_value*.
- The cycle mark column is automatically added to the column list for the *query_name*.
- A row is considered to form a cycle if one of its ancestor rows has the same values for the cycle columns.

If you omit the CYCLE clause, then the recursive WITH clause returns an error if cycles are discovered. In this case, a row forms a cycle if one of its ancestor rows has the same values for all the columns in the column alias list for *query_name* that are referenced in the WHERE clause of the recursive member.

Restrictions on Subquery Factoring

This clause is subject to the following restrictions:

- You can specify only one *subquery_factoring_clause* in a single SQL statement. Any *query_name* defined in the *subquery_factoring_clause* can be used in any subsequent named query block in the *subquery_factoring_clause*.
- In a compound query with set operators, you cannot use the *query_name* for any of the component queries, but you can use the *query_name* in the FROM clause of any of the component queries.
- You cannot specify duplicate names in the column alias list for *query_name*.
- The name used for the *ordering_column* has to be different from the name used for *cycle_mark_c_alias*.

- The *ordering_column* and cycle mark column names cannot already be in the column alias list for *query_name*.

📘 See Also

- *Oracle AI Database Concepts* for information about inline views
- "[Subquery Factoring: Example](#)"
- "[Recursive Subquery Factoring: Examples](#)"

subav_factoring_clause

With the *subav_factoring_clause*, you can define a transitory analytic view that filters fact data prior to aggregation or adds calculated measures to a query of an analytic view. The *subav_name* argument assigns a name to the transitory analytic view. You can then reference the transitory analytic view multiple places in the query by specifying *subav_name*. The *subav_name* is subject to the same naming conventions and restrictions as database schema objects. Refer to "[Database Object Naming Rules](#)" for information on database object names.

You can specify this clause in any top-level SELECT statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries.

The *sub_av_clause* argument defines a transitory analytic view.

sub_av_clause

With the USING keyword, specify the name of an analytic view, which may be a transitory analytic view previously defined in the WITH clause or it may be a persistent analytic view. A persistent analytic view is defined in a CREATE ANALYTIC VIEW statement. If the analytic view is a persistent one, then the current user must have select access on it.

📘 See Also

[Analytic Views: Examples](#)

hierarchies_clause

The *hierarchies_clause* specifies the hierarchies of the base analytic view that the results of the transitory analytic view are dimensioned by. With the HIERARCHIES keyword, specify the alias of one or more hierarchies of the base analytic view.

If you do not specify a HIERARCHIES clause, then the default hierarchies of the base analytic view are used.

filter_clauses

You may specify a given *hier_alias* in at most one *filter_clause*.

filter_clause

The filter clause applies the specified predicate condition to the fact table, which reduces the number of rows returned from the table before aggregation of the measure values. The predicate may contain any SQL row function or operation. The predicate may refer to any

attribute of the specified hierarchy or it may refer to a measure of the analytic view if you specify the MEASURES keyword.

For example, the following clause restricts the aggregation of measure values to those for the first and second quarters of every year of a time hierarchy.

```
FILTER FACT (time_hier TO quarter_of_year IN (1,2))
```

If you then select from the transitory analytic view the sales for the years 2000 and 2001, the values returned are the aggregated values of the first and second quarters only.

An example of specifying a predicate for a measure in the filter clause is the following.

```
FILTER FACT (MEASURES TO sales BETWEEN 100 AND 200)
```

attr_dim_alias

The alias of an attribute dimension in the base analytic view. The USER_ANALYTIC_VIEW_DIMENSIONS view contains the aliases of the attribute dimensions in an analytic view.

hier_alias

The alias of a hierarchy in the base analytic view. The USER_ANALYTIC_VIEW_HIERS view contains the aliases of the hierarchies in an analytic view.

add_meas_clause

With the ADD MEASURES keywords, you may add calculated measures to the transitory analytic view.

calc_meas_clause

Specify a name for the calculated measure and an analytic view expression that specifies values for the calculated measure. The analytic view expression can be any valid *calc_meas_expression* as described in [Analytic View Expressions](#). For example, the following adds a calculated measure named "share_sales."

```
ADD MEASURES (share_sales AS (SHARE_OF(sales HIERARCHY time_hier PARENT)))
```

hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

See Also

"[Hints](#)" for the syntax and description of hints

DISTINCT | UNIQUE

Specify DISTINCT or UNIQUE if you want the database to return only one copy of each set of duplicate rows selected. These two keywords are synonymous. Duplicate rows are those with matching values for each expression in the select list.

Restrictions on DISTINCT and UNIQUE Queries

These types of queries are subject to the following restrictions:

- When you specify DISTINCT or UNIQUE, the total number of bytes in all select list expressions is limited to the size of a data block minus some overhead. This size is specified by the initialization parameter DB_BLOCK_SIZE.
- You cannot specify DISTINCT if the *select_list* contains LOB columns.

ALL

Specify ALL if you want the database to return all rows selected, including all copies of duplicates. The default is ALL.

select_list

The *select_list* lets you specify the columns you want to retrieve from the database.

***** (all-column wildcard)

Specify the all-column wildcard (asterisk) to select all columns, excluding pseudocolumns and INVISIBLE columns, from all tables, views, or materialized views listed in the FROM clause. The columns are returned in the order indicated by the COLUMN_ID column of the *_TAB_COLUMNS data dictionary view for the table, view, or materialized view.

If you are selecting from a table rather than from a view or a materialized view, then columns that have been marked as UNUSED by the ALTER TABLE SET UNUSED statement are not selected.

See Also

[ALTER TABLE](#), "[Simple Query Examples](#)", and "[Selecting from the DUAL Table: Example](#)"

query_name.*

Specify *query_name* followed by a period and the asterisk to select all columns from the specified subquery block. For *query_name*, specify a subquery block name already specified in the *subquery_factoring_clause*. You must have specified the *subquery_factoring_clause* in order to specify *query_name* in the *select_list*. If you specify *query_name* in the *select_list*, then you also must specify *query_name* in the *query_table_expression* (FROM clause).

*table.** | *view.** | *materialized view.**

Specify the object name followed by a period and the asterisk to select all columns from the specified table, view, or materialized view. The database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more tables, views, or materialized views is a join.

You can use the schema qualifier to select from a table, view, or materialized view in a schema other than your own. If you omit *schema*, then the database assumes the table, view, or materialized view is in your own schema.

① See Also

["Joins "](#)

t_alias .*

Specify a correlation name (alias) followed by a period and the asterisk to select all columns from the object with that correlation name specified in the FROM clause of the same subquery. The object can be a table, view, materialized view, or subquery. The database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more objects is a join.

expr

Specify an expression representing the information you want to select. A column name in this list can be qualified with *schema* only if the table, view, or materialized view containing the column is qualified with *schema* in the FROM clause. If you specify a member method of an object type, then you must follow the method name with parentheses even if the method takes no arguments.

The expression can also hold a scalar value that can be return values of PL/SQL functions, subqueries that return a single value per row, and SQL macros.

c_alias

Specify an alias for the column expression. The database will use this alias in the column heading of the result set. The AS keyword is optional. The alias effectively renames the select list item for the duration of the query. The alias can be used in the *order_by_clause* but not other clauses in the query.

From Release 23 you can use *c_alias* in *group_by_clause* .

① See Also

- *Oracle AI Database Data Warehousing Guide* for information on using the *expr* AS *c_alias* syntax with the UNION ALL operator in queries of multiple materialized views
- ["About SQL Expressions "](#) for the syntax of *expr*

Restrictions on the Select List

The select list is subject to the following restrictions:

- If you also specify a [group_by_clause](#) in this statement, then this select list can contain only the following types of expressions:
 - Constants
 - Aggregate functions and the functions USER, UID, and SYSDATE
 - Expressions identical to those in the *group_by_clause*. If the *group_by_clause* is in a subquery, then all columns in the select list of the subquery must match the GROUP BY columns in the subquery. If the select list and GROUP BY columns of a top-level query or of a subquery do not match, then the statement results in ORA-00979.

From Release 23 you can group by *position* and *alias*.

- Expressions involving the preceding expressions that evaluate to the same value for all rows in a group
- You can select a rowid from a join view only if the join has one and only one key-preserved table. The rowid of that table becomes the rowid of the view.

① See Also

Oracle AI Database Administrator's Guide for information on key-preserved tables

- If two or more tables have some column names in common, and if you are specifying a join in the FROM clause, then you must qualify column names with names of tables or table aliases.

FROM Clause

Use the optional FROM clause to specify the objects from which data is selected.

You can invoke a polymorphic table function (PTF) in the query block of the FROM clause like other existing table functions. A PTF is a table function whose operands can have more than one type.

With Oracle Database 21c, you can write SQL table macros and use them inside the FROM clause, where it would be legal to call a PL/SQL function. SQL table macros are expressions, typically used in a FROM clause, to act as a sort of polymorphic (parameterized) views. You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

With Oracle AI Database Release 23ai, you can use the GRAPH_TABLE operator as a table expression in the FROM clause.

① See Also

- [GRAPH_TABLE Operator](#)
- *PL/SQL Optimization and Tuning*
- Defining SQL Macros

ONLY

The ONLY clause applies only to views. Specify ONLY if the view in the FROM clause is a view belonging to a hierarchy and you do not want to include rows from any of its subviews.

query_table_expression

Use the *query_table_expression* clause to identify a subquery block, table, view, materialized view, analytic view, hierarchy, partition, or subpartition, or to specify a subquery that identifies the objects. In order to specify a subquery block, you must have specified the subquery block name (*query_name* in the *subquery_factoring_clause* or *subav_name* in the *subav_factoring_clause*).

The analytic view in the expression may be a transitory analytic view defined in the *with_clause* or a persistent analytic view.

① See Also

["Using Subqueries: Examples"](#)

LATERAL

Specify LATERAL to designate *subquery* as a lateral inline view. Within a lateral inline view, you can specify tables that appear to the left of the lateral inline view in the FROM clause of a query. You can specify this left correlation anywhere within *subquery* (such as the SELECT, FROM, and WHERE clauses) and at any nesting level.

Restrictions on LATERAL

Lateral inline views are subject to the following restrictions:

- If you specify LATERAL, then you cannot specify the *pivot_clause*, the *unpivot_clause*, or a pattern in the *table_reference* clause.
- If a lateral inline view contains the *query_partition_clause*, and it is the right side of a join clause, then it cannot contain a left correlation to the left table in the join clause. However, it can contain a left correlation to a table to its left in the FROM clause that is not the left table.
- A lateral inline view cannot contain a left correlation to the first table in a right outer join or full outer join.

① See Also

["Using Lateral Inline Views: Example"](#)

inline_external_table

Specify this clause to inline an external table in a query. You must specify the table columns and properties for the external table that will be inlined in the query.

inline_external_table_properties

This clause extends the *external_table_data_props* with the REJECT LIMIT and access_driver_type options. Use this clause to specify the properties of the external table.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects.

modified_external_table

You can use this clause to override some external table properties specified by the CREATE TABLE or ALTER TABLE statements from within a query.

You can override external table parameters at runtime.

Restrictions

- You must specify the key words EXTERNAL MODIFY in the query. If you do not specify the keywords, you will see a Missing or invalid option error.
- You must reference an external table in the query. If you do not, you will see an error.

- You must specify at least *one* property in the query. One of DEFAULT DIRECTORY, LOCATION, ACCESS PARAMETERS, or REJECT LIMIT.
- If you specify more than one external table properties, they must be listed in order. First the DEFAULT DIRECTORY must be specified, followed by the ACCESS PARAMETERS, LOCATION and REJECT LIMIT. Otherwise an error will be raised.
- In the DEFAULT DIRECTORY clause, you must specify only one proper default directory. Otherwise a Missing DEFAULT keyword error will occur.
- You must enclose a filename in the LOCATION clause within quotes. Otherwise a Missing keyword error will occur. Note that the access driver will decide whether or not to allow a LOCATION clause in the query. If the clause is disallowed for a particular access driver, an error will be raised.
- For ORACLE_LOADER and ORACLE_DATAPUMP access drivers, the external file location in the LOCATION clause must be specified in the following format: directory: location, i.e, the directory and location must be separated by a colon. Multiple locations in the clause must be separated by a comma. Otherwise, a Missing keyword error will occur.
- Note that LOCATION will be made optional in CREATE TABLE, and must be specified either when creating or querying the external table. Otherwise an error will be raised in the access driver.
- When populating external data using ORACLE DATAPUMP via CTAS, the external file location must be specified. This will be the only case where LOCATION clause is mandatory in CREATE TABLE.
- When overriding access parameters, a proper access parameter list must be provided in the ACCESS PARAMETERS clause, with enclosing parentheses.

Note that the syntax and allowable values for the access parameters in the *modified_external_table* clause are the same as for the external table DDL for each access driver. For more see *Oracle AI Database Utilities* for additional details regarding syntax and permissible values.

- If you specify the REJECT LIMIT, then it must either be UNLIMITED or some valid value that is within range. Otherwise a Reject limit out of range error will be raised.

modify_external_table_properties

You can specify the external table properties that you want to modify at run time using this clause. The parameters that you can modify are DEFAULT DIRECTORY, LOCATION, ACCESS PARAMETERS (BADFILE, LOGFILE, DISCARDFILE) and REJECT LIMIT.

Example: Overriding External Table Parameters in a Query

```
SELECT * FROM
sales_external EXTERNAL MODIFY (LOCATION 'sales_9.csv' REJECT LIMIT UNLIMITED);
```

flashback_query_clause

Use the *flashback_query_clause* to retrieve data from a table, view, or materialized view based on time dimensions associated with the data.

This clause implements SQL-driven Flashback, which lets you specify the following:

- A different system change number or timestamp for each object in the select list, using the clauses VERSIONS BETWEEN { SCN | TIMESTAMP } or VERSIONS AS OF { SCN | TIMESTAMP }. You can also implement session-level Flashback using the DBMS_FLASHBACK package.

- A valid time period for each object in the select list, using the clauses `VERSIONS PERIOD FOR` or `AS OF PERIOD FOR`. You can also implement valid-time session-level Flashback using the `DBMS_FLASHBACK_ARCHIVE` package.

A Flashback Query lets you retrieve a history of changes made to a row. You can retrieve the corresponding identifier of the transaction that made the change using the `VERSIONS_XID` pseudocolumn. You can also retrieve information about the transaction that resulted in a particular row version by issuing an Oracle Flashback Transaction Query. You do this by querying the `FLASHBACK_TRANSACTION_QUERY` data dictionary view for a particular transaction ID.

VERSIONS BETWEEN { SCN | TIMESTAMP }

Specify `VERSIONS BETWEEN` to retrieve multiple versions of the rows returned by the query. The database returns all committed versions of the rows that existed between two SCNs or between two timestamp values. The first specified SCN or timestamp must be earlier than the second specified SCN or timestamp. The rows returned include deleted and subsequently reinserted versions of the rows.

- Specify `VERSIONS BETWEEN SCN ...` to retrieve the versions of the row that existed between two SCNs. Both expressions must evaluate to a number and cannot evaluate to `NULL`. `MINVALUE` and `MAXVALUE` resolve to the SCN of the oldest and most recent data available, respectively.
- Specify `VERSIONS BETWEEN TIMESTAMP ...` to retrieve the versions of the row that existed between two timestamps. Both expressions must evaluate to a timestamp value and cannot evaluate to `NULL`. `MINVALUE` and `MAXVALUE` resolve to the timestamp of the oldest and most recent data available, respectively.

AS OF { SCN | TIMESTAMP }

Specify `AS OF` to retrieve the single version of the rows returned by the query at a particular change number (SCN) or timestamp. If you specify `SCN`, then *expr* must evaluate to a number. If you specify `TIMESTAMP`, then *expr* must evaluate to a timestamp value. In either case, *expr* cannot evaluate to `NULL`. The database returns rows as they existed at the specified system change number or time.

The database provides a group of version query pseudocolumns that let you retrieve additional information about the various row versions. Refer to "[Version Query Pseudocolumns](#)" for more information.

When both clauses are used together, the `AS OF` clause determines the SCN or moment in time from which the database issues the query. The `VERSIONS` clause determines the versions of the rows as seen from the `AS OF` point. The database returns null for a row version if the transaction started before the first `BETWEEN` value or ended after the `AS OF` point.

VERSIONS PERIOD FOR

Specify `VERSIONS PERIOD FOR` to retrieve rows from *table* based on whether they are considered valid during the specified time period. In order to use this clause, *table* must support Temporal Validity.

- For *valid_time_column*, specify the name of the valid time dimension column for *table*.
- Use the `BETWEEN` clause to specify the time period during which rows are considered valid. Both expressions must evaluate to a timestamp value and cannot evaluate to `NULL`. `MINVALUE` resolves to the earliest date or timestamp in the start time column of *table*. `MAXVALUE` resolves to latest date or timestamp in the end time column of *table*.

AS OF PERIOD FOR

Specify `AS OF PERIOD FOR` to retrieve rows from *table* based on whether they are considered valid as of the specified time. In order to use this clause, *table* must support Temporal Validity.

- For *valid_time_column*, specify the name of the valid time dimension column for *table*.
- Use *expr* to specify the time as of which rows are considered valid. The expression must evaluate to a timestamp value and cannot evaluate to NULL.

① See Also

- *Oracle AI Database Development Guide* for more information on Temporal Validity
- `CREATE TABLE` [period_definition](#) to learn how to configure a table to support Temporal Validity and for information about the *valid_time_column*, start time column, and end time column

Note on Flashback Queries

When performing a flashback query, the database might not use query optimizations that it would use for other types of queries, which could have a negative impact on performance. In particular, this occurs when you specify multiple flashback queries in a hierarchical query.

Restrictions on Flashback Queries

These queries are subject to the following restrictions:

- You cannot specify a column expression or a subquery in the expression of the `AS OF` clause.
- You cannot specify the `AS OF` clause if you have specified the *for_update_clause*.
- You cannot use the `AS OF` clause in the defining query of a materialized view.
- You cannot use the `VERSIONS` clause in flashback queries to temporary or external tables, or tables that are part of a cluster.
- You cannot use the `VERSIONS` clause in flashback queries to views. However, you can use the `VERSIONS` syntax in the defining query of a view.
- You cannot specify the *flashback_query_clause* if you have specified *query_name* in the *query_table_expression*.

① See Also

- *Oracle AI Database Development Guide* for more information on Oracle Flashback Query
- ["Using Flashback Queries: Example"](#)
- *Oracle AI Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for information about session-level Flashback using the `DBMS_FLASHBACK` package
- *Oracle AI Database Administrator's Guide* and to the description of *Oracle AI Database Reference* `FLASHBACK_TRANSACTION_QUERY` for more information about transaction history

partition_extension_clause

For PARTITION or SUBPARTITION, specify the name or key value of the partition or subpartition within *table* from which you want to retrieve data.

For range- and list-partitioned data, as an alternative to this clause, you can specify a condition in the WHERE clause that restricts the retrieval to one or more partitions of *table*. The database will interpret the condition and fetch data from only those partitions. It is not possible to formulate such a WHERE condition for hash-partitioned data.

① See Also

["References to Partitioned Tables and Indexes "](#) and ["Selecting from a Partition: Example"](#)

dblink

For *dblink*, specify the complete or partial name for a database link to a remote database where the table, view, or materialized view is located. This database need not be an Oracle database.

① See Also

- ["References to Objects in Remote Databases "](#) for more information on referring to database links
- ["Distributed Queries "](#) for more information about distributed queries and ["Using Distributed Queries: Example"](#)

If you omit *dblink*, then the database assumes that the table, view, or materialized view is on the local database.

Restrictions on Database Links

Database links are subject to the following restrictions:

- You cannot query a user-defined type or an object REF on a remote table.
- You cannot query columns of type ANYTYPE, ANYDATA, or ANYDATASET from remote tables.

table | view | materialized_view | analytic_view | hierarchy

Specify the name of a table, view, materialized view, analytic view, or hierarchy from which data is selected.

analytic_view

A persistent analytic view defined with the CREATE ANALYTIC VIEW statement or a transitory analytic view defined in a WITH clause.

 See Also

[Analytic Views: Examples](#)

hierarchy

A hierarchy defined with the CREATE HIERARCHY statement.

sample_clause

The *sample_clause* lets you instruct the database to select from a random sample of data from the table, rather than from the entire table.

 See Also

["Selecting a Sample: Examples"](#)

BLOCK

BLOCK instructs the database to attempt to perform random block sampling instead of random row sampling.

Block sampling is possible only during full table scans or index fast full scans. If a more efficient execution path exists, then the database does not perform block sampling. If you want to guarantee block sampling for a particular table or index, then use the FULL or INDEX_FFS hint.

Beginning with Oracle Database 12c Release 2 (12.2.), you can specify block sampling for external tables. In earlier releases, specifying block sampling for external tables had no effect; row sampling was performed.

sample_percent

For *sample_percent*, specify the percentage of the total row or block count to be included in the sample. The value must be in the range .000001 to, but not including, 100. This percentage indicates the probability of each row, or each cluster of rows in the case of block sampling, being selected as part of the sample. It does not mean that the database will retrieve exactly *sample_percent* of the rows of *table*.

 Warning

The use of statistically incorrect assumptions when using this feature can lead to incorrect or undesirable results.

SEED *seed_value*

Specify this clause to instruct the database to attempt to return the same sample from one execution to the next. The *seed_value* must be an integer between 0 and 4294967295. If you omit this clause, then the resulting sample will change from one execution to the next.

Restrictions on *sample_clause*

The following restrictions apply to the SAMPLE clause:

- You cannot specify the `SAMPLE` clause in a subquery in a DML statement.
- You can specify the `SAMPLE` clause in a query on a base table, a container table of a materialized view, or a view that is key preserving. You cannot specify this clause on a view that is not key preserving.

subquery_restriction_clause

The *subquery_restriction_clause* lets you restrict the subquery in one of the following ways:

WITH READ ONLY

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify `WITH CHECK OPTION` to indicate that the database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

CONSTRAINT *constraint*

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

① See Also

["Using the WITH CHECK OPTION Clause: Example"](#)

table_collection_expression

The *table_collection_expression* lets you inform Oracle that the value of *collection_expression* should be treated as a table for purposes of query and DML operations. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

① Note

In earlier releases of Oracle, when *collection_expression* was a subquery, *table_collection_expression* was expressed as `THE subquery`. That usage is now deprecated.

The *collection_expression* can reference columns of tables defined to its left in the `FROM` clause. This is called **left correlation**. Left correlation can occur only in *table_collection_expression*. Other subqueries cannot contain references to columns defined outside the subquery.

The optional (+) lets you specify that *table_collection_expression* should return a row with all fields set to null if the collection is null or empty. The (+) is valid only if *collection_expression* uses left correlation. The result is similar to that of an outer join.

When you use the (+) syntax in the WHERE clause of a subquery in an UPDATE or DELETE operation, you must specify two tables in the FROM clause of the subquery. The database ignores the outer join syntax unless there is a join in the subquery itself.

① See Also

- ["Outer Joins "](#)
- ["Table Collections: Examples"](#) and ["Collection Unnesting: Examples"](#)

t_alias

Specify a **correlation name**, which is an alias for the table, view, materialized view, or subquery for evaluating the query. This alias is required if the select list references any object type attributes or object type methods. Correlation names are most often used in a correlated query. Other references to the table, view, or materialized view throughout the query must refer to this alias.

① See Also

- ["Using Correlated Subqueries: Examples"](#)

pivot_clause

The *pivot_clause* lets you write cross-tabulation queries that rotate rows into columns, aggregating data in the process of the rotation. The output of a pivot operation typically includes more columns and fewer rows than the starting data set. The *pivot_clause* performs the following steps:

1. The *pivot_clause* computes the aggregation functions specified at the beginning of the clause. Aggregation functions must specify a GROUP BY clause to return multiple values, yet the *pivot_clause* does not contain an explicit GROUP BY clause. Instead, the *pivot_clause* performs an implicit GROUP BY. The implicit grouping is based on all the columns not referred to in the *pivot_clause*, along with the set of values specified in the *pivot_in_clause*). If you specify more than one aggregation function, then you must provide aliases for at least all but one of the aggregation functions.
2. The grouping columns and aggregated values calculated in Step 1 are configured to produce the following cross-tabular output:
 - a. All the implicit grouping columns not referred to in the *pivot_clause*, followed by
 - b. New columns corresponding to values in the *pivot_in_clause*. Each aggregated value is transposed to the appropriate new column in the cross-tabulation. If you specify the XML keyword, then the result is a single new column that expresses the data as an XML string. The database generates a name for each new column. If you do not provide an alias for an aggregation function, then the database uses each pivot column value as the name for each new column to which that aggregated value is transposed. If you provide an alias for an aggregation function, then the database generates a name for each new column to which that aggregated value is transposed

by concatenating the pivot column name, the underscore character (`_`), and the aggregation function alias. If a generated column name exceeds the maximum length of a column name, then an ORA-00918 error is returned. To avoid this issue, specify a shorter alias for the pivot column heading, the aggregation function, or both.

The subclauses of the *pivot_clause* have the following semantics:

XML

The optional XML keyword generates XML output for the query. The XML keyword permits the *pivot_in_clause* to contain either a subquery or the wildcard keyword ANY. Subqueries and ANY wildcards are useful when the *pivot_in_clause* values are not known in advance. With XML output, the values of the pivot column are evaluated at execution time. You cannot specify XML when you specify explicit pivot values using expressions in the *pivot_in_clause*.

When XML output is generated, the aggregate function is applied to each distinct pivot value, and the database returns a column of XMLType containing an XML string for all value and measure pairs.

expr

For *expr*, specify an expression that evaluates to a constant value of a pivot column. You can optionally provide an alias for each pivot column value. If there is no alias, the column heading becomes a quoted identifier.

subquery

A subquery is used only in conjunction with the XML keyword. When you specify a subquery, all values found by the subquery are used for pivoting. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the *pivot_in_clause*, the subquery produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. The XML string for each output row includes all pivot values found by the subquery, even if there are no corresponding rows in the input data.

The subquery must return a list of unique values at the execution time of the pivot query. If the subquery does not return a unique value, then the database raises a run-time error. Use the DISTINCT keyword in the subquery if you are not sure the query will return unique values.

ANY

The ANY keyword is used only in conjunction with the XML keyword. The ANY keyword acts as a wildcard and is similar in effect to *subquery*. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the *pivot_in_clause*, the ANY keyword produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. However, in contrast to the behavior when you specify *subquery*, the ANY wildcard produces an XML string for each output row that includes only the pivot values found in the input data corresponding to that row.

See Also

unpivot_clause

The *unpivot_clause* rotates columns into rows.

- The `INCLUDE | EXCLUDE NULLS` clause gives you the option of including or excluding null-valued rows. `INCLUDE NULLS` causes the unpivot operation to include null-valued rows; `EXCLUDE NULLS` eliminates null-values rows from the return set. If you omit this clause, then the unpivot operation excludes nulls.
- For *column*, specify a name for each output column that will hold measure values, such as `sales_quantity`.
- In the *pivot_for_clause*, specify a name for each output column that will hold descriptor values, such as `quarter` or `product`.
- In the *unpivot_in_clause*, specify the input data columns whose names will become values in the output columns of the *pivot_for_clause*. These input data columns have names specifying a category value, such as `Q1`, `Q2`, `Q3`, `Q4`. The optional `AS` clause lets you map the input data column names to the specified *literal* values in the output columns.

The unpivot operation turns a set of value columns into one column. Therefore, the data types of all the value columns must be in the same data type group, such as numeric or character.

- If all the value columns are `CHAR`, then the unpivoted column is `CHAR`. If any value column is `VARCHAR2`, then the unpivoted column is `VARCHAR2`.
- If all the value columns are `NUMBER`, then the unpivoted column is `NUMBER`. If any value column is `BINARY_DOUBLE`, then the unpivoted column is `BINARY_DOUBLE`. If no value column is `BINARY_DOUBLE` but any value column is `BINARY_FLOAT`, then the unpivoted column is `BINARY_FLOAT`.

containers_clause

The `CONTAINERS` clause is useful in a multitenant container database (CDB). This clause lets you query data in the specified table or view across all containers in a CDB.

- To query data in a CDB, you must be a common user connected to the CDB root, and the table or view must exist in the root and all PDBs. The query returns all rows from the table or view in the CDB root and in all open PDBs.
- To query data in an application container, you must be a common user connected to the application root, and the table or view must exist in the application root and all PDBs in the application container. The query returns all rows from the table or view in the application root and in all open PDBs in the application container.

The table or view must be in your own schema. It is not necessary to specify *schema*, but if you do then you must specify your own schema.

The query returns all rows from the table or view in the root and in all open PDBs, except PDBs that are open in `RESTRICTED` mode. If the queried table or view does not already contain a `CON_ID` column, then the query adds a `CON_ID` column to the query result, which identifies the container whose data a given row represents.

① See Also

- [CONTAINERS Hint](#)
- *Oracle AI Database Administrator's Guide* for more information on the CONTAINERS clause

shards_clause

Use the *shards_clause* to query Oracle supplied objects such as V\$, DBA/USER/ALL views, and dictionary tables across shards. You can execute a query with the *shards_clause* only on the shard catalog database.

This feature enables easier centralized management by providing the ability to execute queries across all shards from a central shard catalog.

values_clause

You can use the *values_clause* in the FROM and *with_clause* of SELECT as a table value constructor (TVC).

Each table value constructor contains a set of row value expressions (RVE). The elements in each row expression should be homogeneous in number and their type must be compatible.

The *c_alias* or column alias is the name of the column corresponding to each expression in an RVE.

TVCs in the FROM clause of select statements can be used as table expressions.

Example: Using the Values Constructor in the FROM Clause of SELECT

```
SELECT *  
      FROM ( VALUES (1, 'SCOTT'),  
                    (2, 'SMITH'),  
                    (3, 'JOHN' )  
            ) t1 (employee_id, first_name);
```

The example above creates an in-line table t1 with two columns *employee_id* and *first_name* and three rows.

If you use the *values_clause* with the [with_clause::=](#), you must specify the column alias. Each column alias must correspond to the column produced by the TVC. In this case, the TVC replaces the subquery.

Example: Using the Values Constructor in the With_Clause of SELECT:

```
WITH X(foo, bar, baz) AS (  
    VALUES (0, 1, 2), (3, 4, 5), (6, 7, 8) ) SELECT * FROM X;
```

The table and column aliases (*t_alias* and *c_alias*) are required unless you use *values_clause* with *with_clause* in SELECT.

Restrictions

- If multiple RVEs are specified, then each RVE should have the same cardinality. This means that each RVE must have the same number of elements.

- Each element of the RVE can be a valid SQL expression that includes a column name, scalar valued subquery, bind variable, or any other expression that evaluates to a single value.
- The type of the expression or a constant at the corresponding positions of RVE in a TVC should be implicitly convertible to the most general type following normal SQL type conversion rules. The type of expression that will be inferred will be the most general type of expression at the same position in all RVEs that constitute the TVC.
- If a scalar valued subquery is used to compute the value of an element in a RVE then the select list of scalar valued subquery can contain exactly one expression.
- If RVE is used in an UPDATE, or MERGE statement, then the keyword DEFAULT can be specified in a RVE for each position to indicate to the SQL engine that the default column value should be used for this column.
- The execution plan will have a new section that appears only when the TVC has RVEs consisting of constant values.
- If the types of the corresponding elements in a RVE in a TVC have different constraints, then the type of the column will be the union of all the constraints or the most relaxed constraint.
- An error will be thrown if a TVC, that consists of more than one RVE, is used in a place where a scalar valued subquery is expected.
- The parallel behavior will be similar to union all queries on DUAL. TVC will not impact parallel behavior.
- RVEs cannot be nested, that is, a RVE cannot contain another RVE.
- The maximum number of columns produced by the *with_clause* will be the same as the maximum number of columns in a database table.
- NDV and other statistics that are computed by the optimizer will be similar to a union of all queries on DUAL.
- The TVC clause will not have any restriction on number of RVEs other than the restriction imposed by available memory.
- The elimination of UNION ALL branches on a predicate will be similar to UNION ALL queries with DUAL.

join_clause

Use the appropriate *join_clause* syntax to identify tables that are part of a join from which to select data. The *inner_cross_join_clause* lets you specify an inner or cross join. The *outer_join_clause* lets you specify an outer join. The *cross_outer_apply_clause* lets you specify a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support.

When you join more than two row sources, you can use parentheses to override default precedence. For example, the following syntax:

```
SELECT ... FROM a JOIN (b JOIN c) ...
```

results in a join of b and c, and then a join of that result set with a.

① See Also

"[Joins](#)" for more information on joins, "[Using Join Queries: Examples](#)", "[Using Self Joins: Example](#)", and "[Using Outer Joins: Examples](#)"

inner_cross_join_clause

Inner joins return only those rows that satisfy the join condition.

INNER

Specify **INNER** to explicitly specify an inner join.

JOIN

The **JOIN** keyword explicitly states that a join is being performed. You can use this syntax to replace the comma-delimited table expressions used in **WHERE** clause joins with **FROM** clause join syntax.

ON condition

Use the **ON** clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the **WHERE** clause.

USING (column)

When you are specifying an equijoin of columns that have the same name in both tables, the **USING column** clause indicates the columns to be used. You can use this clause only if the join columns in both tables have the same name. Within this clause, do not qualify the column name with a table name or table alias.

CROSS

The **CROSS** keyword indicates that a cross join is being performed. A cross join produces the cross-product of two relations and is essentially the same as the comma-delimited database notation.

NATURAL

The **NATURAL** keyword indicates that a natural join is being performed. Refer to [NATURAL](#) for the full semantics of this clause.

outer_join_clause

Outer joins return all rows that satisfy the join condition and also return some or all of those rows from one table for which no rows from the other satisfy the join condition. You can specify two types of outer joins: a conventional outer join using the *table_reference* syntax on both sides of the join, or a partitioned outer join using the *query_partition_clause* on one side or the other. A partitioned outer join is similar to a conventional outer join except that the join takes place between the outer table and each partition of the inner table. This type of join lets you selectively make sparse data more dense along the dimensions of interest. This process is called **data densification**.

query_partition_clause

The *query_partition_clause* lets you define a **partitioned outer join**. Such a join extends the conventional outer join syntax by applying the outer join to partitions returned by the query. The database creates a partition of rows for each expression you specify in the **PARTITION BY** clause. The rows in each query partition have same value for the **PARTITION BY** expression.

The *query_partition_clause* can be on either side of the outer join. The result of a partitioned outer join is a UNION of the outer joins of each of the partitions in the partitioned result set and the table on the other side of the join. This type of result is useful for filling gaps in sparse data, which simplifies analytic calculations.

If you omit this clause, then the database treats the entire table expression—everything specified in *table_reference*—as a single partition, resulting in a conventional outer join.

To use the *query_partition_clause* in an analytic function, use the upper branch of the syntax (without parentheses). To use this clause in a model query (in the *model_column_clauses*) or a partitioned outer join (in the *outer_join_clause*), use the lower branch of the syntax (with parentheses).

Restrictions on Partitioned Outer Joins

Partitioned outer joins are subject to the following restrictions:

- You can specify the *query_partition_clause* on either the right or left side of the join, but not both.
- You cannot specify a FULL partitioned outer join.
- If you specify the *query_partition_clause* in an outer join with an ON clause, then you cannot specify a subquery in the ON condition.

① See Also

["Using Partitioned Outer Joins: Examples"](#)

NATURAL

The NATURAL keyword indicates that a natural join is being performed. A natural join is based on all columns in the two tables that have the same name. It selects rows from the two tables that have equal values in the relevant columns. If two columns with the same name do not have compatible data types, then an error is raised. When specifying columns that are involved in the natural join, do not qualify the column name with a table name or table alias.

On occasion, the table pairings in natural or cross joins may be ambiguous. For example, consider the following join syntax:

```
a NATURAL LEFT JOIN b LEFT JOIN c ON b.c1 = c.c1
```

This example can be interpreted in either of the following ways:

```
a NATURAL LEFT JOIN (b LEFT JOIN c ON b.c1 = c.c1)
(a NATURAL LEFT JOIN b) LEFT JOIN c ON b.c1 = c.c1
```

To avoid this ambiguity, you can use parentheses to specify the pairings of joined tables. In the absence of such parentheses, the database uses left associativity, pairing the tables from left to right.

Restriction on Natural Joins

You cannot specify a LOB column, columns of ANYTYPE, ANYDATA, or ANYDATASET, or a collection column as part of a natural join.

outer_join_type

The *outer_join_type* indicates the kind of outer join being performed:

- Specify **RIGHT** to indicate a right outer join.
- Specify **LEFT** to indicate a left outer join.
- Specify **FULL** to indicate a full or two-sided outer join. In addition to the inner join, rows from both tables that have not been returned in the result of the inner join will be preserved and extended with nulls.
- You can specify the optional **OUTER** keyword following **RIGHT**, **LEFT**, or **FULL** to explicitly clarify that an outer join is being performed.

ON condition

Use the **ON** clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the **WHERE** clause.

Restriction on the ON condition Clause

You cannot specify this clause with a **NATURAL** outer join.

USING column

In an outer join with the **USING** clause, the query returns a single column that coalesces the two matching columns in the join. The coalesce function is as follows:

`COALESCE (a, b) = a if a NOT NULL, else b.`

Therefore:

- A left outer join returns all the common column values from the left table in the **FROM** clause.
- A right outer join returns all the common column values from the right table in the **FROM** clause.
- A full outer join returns all the common column values from both joined tables.

Restriction on the USING column Clause

The **USING column** clause is subject to the following restrictions:

- Within this clause, do not qualify the column name with a table name or table alias.
- You cannot specify a LOB column or a collection column in the **USING column** clause.
- You cannot specify this clause with a **NATURAL** outer join.

See Also

- "[Outer Joins](#)." for additional rules and restrictions pertaining to outer joins
- *Oracle AI Database Data Warehousing Guide* for a complete discussion of partitioned outer joins and data densification
- "[Using Outer Joins: Examples](#)"

cross_outer_apply_clause

This clause allows you to perform a variation of an ANSI **CROSS JOIN** or an ANSI **LEFT OUTER JOIN** with left correlation support. You can specify a *table_reference* or *collection_expression* to the right of the **APPLY** keyword. The *table_reference* can be a table, inline view, or **TABLE** collection expression. The *collection_expression* can be a

subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. The *table_reference* or *collection_expression* can reference columns of tables defined in the FROM clause to the left of the APPLY keyword. This is called left correlation.

- Specify CROSS APPLY to perform a variation of an ANSI CROSS JOIN. Only rows from the table on the left side of the join that produce a result set from *table_reference* or *collection_expression* are returned.
- Specify OUTER APPLY to perform a variation of an ANSI LEFT OUTER JOIN. All rows from the table on the left side of the join are returned. Rows that do not produce a result set from *table_reference* or *collection_expression* have the NULL value in the corresponding column(s).

Restriction on the *cross_outer_apply_clause*

The *table_reference* cannot be a lateral inline view.

❶ See Also

[Using CROSS APPLY and OUTER APPLY Joins: Examples](#)

inline_analytic_view

An inline analytic view is a transitory analytic view that is specified in the FROM clause. To create an inline analytic view, use the ANALYTIC VIEW keyword and specify a *sub_av_clause* that defines the analytic view. Optionally, you may specify an *inline_av_alias*, which is an alias for the inline analytic view. The rules for the *inline_av_alias* are the same as the rules for an inline view alias.

❶ See Also

[Analytic Views: Examples](#)

JOIN TO ONE Clauses

The clauses *join_to_one_from_clause*, *non_join_to_one_from_clause*, and *join_to_one* have three goals:

- Make joins simpler to write.
The ON clause of *jto_table_with_optional_on_clause* is optional when a declared foreign key implies it unambiguously.
The *jto_on_condition* is like any other ON condition, except that it does not allow subqueries.
- Make joined results easier to reason about. Rows from the leftmost table map cleanly to query result rows, and joins to the right must be unique.
- Prevent join patterns that often produce incorrect results. When you use JOIN TO ONE for all joins in a query, you avoid common sources of serious hard-to-find SQL errors.

If the query uses *join_to_one_clause* for all joins, meaning you do not add additional joins after the closing parenthesis of the JOIN TO ONE (...) clause, then the first table listed (the leftmost table) is the Row-Widened Table (RWT). Every join inside the parentheses, interpreted

logically from left to right from the RWT, must be unique for the data encountered at runtime. If the database finds a non-unique join at runtime, it raises an error.

The optimizer may choose an execution plan that does not follow the left-to-right order. That does not change the logical requirement: the query must be row-widening only from the RWT perspective, meaning joins add columns to RWT rows without multiplying them.

As a result, before any aggregation, the query returns rows that map one-to-one to a subset of the RWT rows. This one-to-one mapping is a key property of most correct application queries. While this useful property is not too difficult to assure with a handful of joins, as queries grow more complex, it becomes progressively harder to assure.

For a recommended, detailed explanation of why this matters and how to use `JOIN TO ONE` effectively, see *Building Queries with Correct Joins More Easily* of the *Database Development Guide*.

jto_join_spec

The default join type for all joins in the parentheses following `JOIN TO ONE` is `LEFT OUTER JOIN`. You do not need to specify it when you want a non-filtering, unique join. The database chose this default because `INNER JOINS` often filter rows unintentionally.

With `JOIN TO ONE`, row filtering becomes explicit. It happens through:

- an explicitly specified `INNER JOIN` (`JOIN`, alone, is invalid)
- or predicates in the `WHERE` clause.

`LEFT OUTER JOIN` and `OUTER JOIN` have the same effect. `INNER JOIN` discards rows from the left side when no match exists on the right side.

Regardless of join type, all joins inside the parentheses must be unique on the right side. If not, the database raises a runtime error to highlight a join that is non-unique due to coding mistakes or bad data.

jto_table_with_optional_on_clause

Inside the parentheses that follow `JOIN TO ONE`, `ON` clauses are optional. If you provide an `ON` clause, the database uses it as written. If you omit the `ON` clause, the database attempts to infer it by searching tables to the left for a declared foreign key that references the primary key or a unique key of the table being joined.

The database can infer the `ON` clause only when it finds exactly one valid foreign key to primary or unique key relationship. If it finds none, or more than one, you must provide an `ON` clause.

If you want a join condition that differs from what the database would infer from declared keys, you must write the full `ON` clause.

jto_list_delimiter

Within the join list inside the parentheses, you can separate elements in either of these ways:

- Use commas when you omit the join type, which implies the default `LEFT OUTER JOIN`.
- Specify an explicit join type (for example, `INNER JOIN`). When you do, the join keyword sequence replaces the comma between list elements.

jto_table_expression

This element resembles table expressions in a standard `FROM` clause, with one key restriction: inline views and CTEs (common table expressions from the `WITH` clause) are not allowed.

joined_table_view_mv

Objects referenced inside a JOIN TO ONE clause must be one of the following:

- a physical table
- a materialized view
- a named view

They cannot be inline views or CTEs. If you join to a named view, Oracle may incur runtime overhead to verify that the join is unique.

where_clause

The WHERE condition lets you restrict the rows selected to those that satisfy one or more conditions. For *condition*, specify any valid SQL condition.

If you omit this clause, then the database returns all rows from the tables, views, or materialized views in the FROM clause.

Note

If this clause refers to a DATE column of a partitioned table or index, then the database performs partition pruning only if:

- You created the table or index partitions by fully specifying the year using the TO_DATE function with a 4-digit format mask, *and*
- You specify the date in the *where_clause* of the query using the TO_DATE function and either a 2- or 4-digit format mask.

You can write macros for scalar expressions and use them inside the *where_clause*, where it would be legal to call a PL/SQL function.

You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

See Also

- [Conditions](#) for the syntax description of *condition*
- ["Selecting from a Partition: Example"](#)
- Defining SQL Macros

hierarchical_query_clause

The *hierarchical_query_clause* lets you select rows in a hierarchical order.

SELECT statements that contain hierarchical queries can contain the LEVEL pseudocolumn in the select list. LEVEL returns the value 1 for a root node, 2 for a child node of a root node, 3 for a grandchild, and so on. The number of levels returned by a hierarchical query may be limited by available user memory.

Oracle processes hierarchical queries as follows:

- A join, if present, is evaluated first, whether the join is specified in the FROM clause or with WHERE clause predicates.
- The CONNECT BY condition is evaluated.
- Any remaining WHERE clause predicates are evaluated.

If you specify this clause, then do not specify either ORDER BY or GROUP BY, because they will destroy the hierarchical order of the CONNECT BY results. If you want to order rows of siblings of the same parent, then use the ORDER SIBLINGS BY clause.

📘 See Also

"[Hierarchical Queries](#)" for a discussion of hierarchical queries and "[Using the LEVEL Pseudocolumn: Examples](#)"

START WITH Clause

Specify a condition that identifies the row(s) to be used as the root(s) of a hierarchical query. The *condition* can be any condition as described in [Conditions](#). The database uses as root(s) all rows that satisfy this condition. If you omit this clause, then the database uses all rows in the table as root rows.

CONNECT BY Clause

Specify a condition that identifies the relationship between parent rows and child rows of the hierarchy. The *condition* can be any condition as described in [Conditions](#). However, it must use the PRIOR operator to refer to the parent row.

📘 See Also

- [Pseudocolumns](#) for more information on LEVEL
- "[Hierarchical Queries](#)" for general information on hierarchical queries
- "[Hierarchical Query: Examples](#)"

group_by_clause

Specify the GROUP BY clause if you want the database to group the selected rows based on the value of *expr(s)* for each row and return a single row of summary information for each group. If this clause contains CUBE or ROLLUP extensions, then the database produces superaggregate groupings in addition to the regular groupings.

Expressions in the GROUP BY clause can contain any columns of the tables, views, or materialized views in the FROM clause, regardless of whether the columns appear in the select list.

The GROUP BY clause groups rows but does not guarantee the order of the result set. To order the groupings, use the ORDER BY clause.

If a column name in the source tables and column alias in the SELECT list are the same, GROUP BY will interpret the identifier as the column name, not the alias.

① See Also

- *Oracle AI Database Data Warehousing Guide* for an expanded discussion and examples of using SQL grouping syntax for data aggregation
- the [GROUP_ID](#), [GROUPING](#), and [GROUPING_ID](#) functions for examples
- "[Using the GROUP BY Clause: Examples](#)"
- [Restrictions for Linguistic Collations](#) for information on implications of how GROUP BY character values are compared linguistically
- Appendix C in *Oracle AI Database Globalization Support Guide* for the collation determination rules for the expressions in the GROUP BY clause

ROLLUP

The ROLLUP operation in the *simple_grouping_clause* groups the selected rows based on the values of the first n , $n-1$, $n-2$, ... 0 expressions in the GROUP BY specification, and returns a single row of summary for each group. You can use the ROLLUP operation to produce **subtotal values** by using it with the SUM function. When used with SUM, ROLLUP generates subtotals from the most detailed level to the grand total. Aggregate functions such as COUNT can be used to produce other kinds of superaggregates.

For example, given three expressions ($n=3$) in the ROLLUP clause of the *simple_grouping_clause*, the operation results in $n+1 = 3+1 = 4$ groupings.

Rows grouped on the values of the first n expressions are called **regular rows**, and the others are called **superaggregate rows**.

① See Also

Oracle AI Database Data Warehousing Guide for information on using ROLLUP with materialized views

CUBE

The CUBE operation in the *simple_grouping_clause* groups the selected rows based on the values of all possible combinations of expressions in the specification. It returns a single row of summary information for each group. You can use the CUBE operation to produce **cross-tabulation values**.

For example, given three expressions ($n=3$) in the CUBE clause of the *simple_grouping_clause*, the operation results in $2^n = 2^3 = 8$ groupings. Rows grouped on the values of n expressions are called **regular rows**, and the rest are called **superaggregate rows**.

① See Also

- *Oracle AI Database Data Warehousing Guide* for information on using CUBE with materialized views
- "[Using the GROUP BY CUBE Clause: Example](#)"

GROUPING SETS

GROUPING SETS are a further extension of the GROUP BY clause that let you specify multiple groupings of data. Doing so facilitates efficient aggregation by pruning the aggregates you do not need. You specify just the desired groups, and the database does not need to perform the full set of aggregations generated by CUBE or ROLLUP. The database computes all groupings specified in the GROUPING SETS clause and combines the results of individual groupings with a UNION ALL operation. The UNION ALL means that the result set can include duplicate rows.

Within the GROUP BY clause, you can combine expressions in various ways:

- To specify **composite columns**, group columns within parentheses so that the database treats them as a unit while computing ROLLUP or CUBE operations.
- To specify **concatenated grouping sets**, separate multiple grouping sets, ROLLUP, and CUBE operations with commas so that the database combines them into a single GROUP BY clause. The result is a cross-product of groupings from each grouping set.

See Also

["Using the GROUPING SETS Clause: Example"](#)

ALL

- ALL is a reserved word, so it cannot be a column name and it cannot be used as a column alias.
- You cannot use ALL with other GROUP BY syntax options. If you specify ALL, then GROUP BY ALL is the only allowed *group_by_clause* syntax. In particular, you cannot specify ROLLUP, CUBE or GROUPING SETS with GROUP BY ALL.
- GROUP BY ALL includes all select list expressions except the following, which are not valid GROUP BY expressions in the GROUP BY clause:
 - group functions or expressions containing group functions
 - scalar subqueries
 - window functions
- GROUP BY ALL also excludes select list expressions that are constants, including NULLs, and binds. The main reason to skip constants is to avoid ambiguity if group by position is enabled.
- GROUP BY ALL does not extract parts of the select list expression for GROUP BY: either the whole expression is included in the GROUP BY or not at all.
- GROUP BY ALL can be used in views and materialized views. The definition query stored in the dictionary for both will contain GROUP BY ALL and not the transformed GROUP BY clause.
- Full text-match rewrite of materialized views with GROUP BY ALL is supported, but partial text-match rewrite is not.
- GROUP BY ALL can be used in a WITH clause query. It is supported wherever the GROUP BY clause is allowed.
- HAVING condition may be specified with GROUP BY ALL.
- GROUP BY ALL is not supported with MODEL clause. If you specify it, the following error is raised: "GROUP BY ALL is not supported with MODEL clause".

- GROUP BY expression limit (1000 or 4k) applies to GROUP BY ALL . If you exceed the limit an error is raised.
- GROUP BY ALL is not supported in a CREATE MATERIALIZED ZONE MAP DDL defining subquery. If you specify it, the following error is raised: "Construct or object GROUP BY ALL clause not allowed for zonemap".

HAVING Clause

Use the HAVING clause to restrict the groups of returned rows to those groups for which the specified *condition* is TRUE. If you omit this clause, then the database returns summary rows for all groups.

Specify GROUP BY and HAVING after the *where_clause* and *hierarchical_query_clause*. If you specify both GROUP BY and HAVING, then they can appear in either order.

With Oracle Database 21c you can write macros for scalar expressions and use them inside the HAVING clause, where it would be legal to call a PL/SQL function.

You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

① See Also

- ["Using the HAVING Condition: Example"](#)
- Defining SQL Macros

Restrictions on the GROUP BY Clause

This clause is subject to the following restrictions:

- You cannot specify LOB columns, nested tables, or varrays as part of *expr*.
- The expressions can be of any form except scalar subquery expressions.
- If the *group_by_clause* references any object type columns, then the query will not be parallelized.
- To group by position, the parameter `group_by_position_enabled` must be set to true, this is false by default

model_clause

The *model_clause* lets you view selected rows as a multidimensional array and randomly access cells within that array. Using the *model_clause*, you can specify a series of cell assignments, referred to as **rules**, that invoke calculations on individual cells and ranges of cells. These rules operate on the results of a query and do not update any database tables.

When using the *model_clause* in a query, the SELECT and ORDER BY clauses must refer only to those columns defined in the *model_column_clauses*.

① See Also

- The syntax description of *expr* in "[About SQL Expressions](#)" and the syntax description of *condition* in [Conditions](#)
- *Oracle AI Database Data Warehousing Guide* for an expanded discussion and examples
- "[The MODEL clause: Examples](#)"

main_model

The *main_model* clause defines how the selected rows will be viewed in a multidimensional array and what rules will operate on which cells in that array.

model_column_clauses

The *model_column_clauses* define and classify the columns of a query into three groups: partition columns, dimension columns, and measure columns. For *expr*, you can specify a column, constant, host variable, single-row function, aggregate function, or any expression involving them. If *expr* is a column, then the column alias (*c_alias*) is optional. If *expr* is not a column, then the column alias is required. If you specify a column alias, then you must use the alias to refer to the column in the *model_rules_clause*, SELECT list, and the query ORDER BY clauses.

PARTITION BY

The PARTITION BY clause specifies the columns that will be used to divide the selected rows into partitions based on the values of the specified columns.

DIMENSION BY

The DIMENSION BY clause specifies the columns that will identify a row within a partition. The values of the dimension columns, along with those of the partition columns, serve as array indexes to the measure columns within a row.

MEASURES

The MEASURES clause identifies the columns on which the calculations can be performed. Measure columns in individual rows are treated like cells that you can reference, by specifying the values for the partition and dimension columns, and update.

cell_reference_options

Use the *cell_reference_options* clause to specify how null and absent values are treated in rules and how column uniqueness is constrained.

IGNORE NAV

When you specify IGNORE NAV, the database returns the following values for the null and absent values of the data type specified:

- Zero for numeric data types
- 01-JAN-2000 for datetime data types
- An empty string for character data types
- Null for all other data types

KEEP NAV

When you specify KEEP NAV, the database returns null for both null and absent cell values. KEEP NAV is the default.

UNIQUE SINGLE REFERENCE

When you specify UNIQUE SINGLE REFERENCE, the database checks only single-cell references on the right-hand side of the rule for uniqueness, not the entire query result set.

UNIQUE DIMENSION

When you specify UNIQUE DIMENSION, the database checks that the PARTITION BY and DIMENSION BY columns form a unique key to the query. UNIQUE DIMENSION is the default.

model_rules_clause

Use the *model_rules_clause* to specify the cells to be updated, the rules for updating those cells, and optionally, how the rules are to be applied and processed.

Each rule represents an assignment and consists of a left-hand side and right-hand side. The left-hand side of the rule identifies the cells to be updated by the right-hand side of the rule. The right-hand side of the rule evaluates to the values to be assigned to the cells specified on the left-hand side of the rule.

UPSERT ALL

UPSERT ALL allows UPSERT behavior for a rule with both positional and symbolic references on the left-hand side of the rule. When evaluating an UPSERT ALL rule, Oracle performs the following steps to create a list of cell references to be upserted:

1. Find the existing cells that satisfy all the symbolic predicates of the cell reference.
2. Using just the dimensions that have symbolic references, find the distinct dimension value combinations of these cells.
3. Perform a cross product of these value combinations with the dimension values specified by way of positional references.

Refer to *Oracle AI Database Data Warehousing Guide* for more information on the semantics of UPSERT ALL.

UPSERT

When you specify UPSERT, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array, and inserts new rows for those that do not exist. UPSERT behavior applies only when positional referencing is used on the left-hand side and a single cell is referenced. UPSERT is the default. Refer to [cell_assignment](#) for more information on positional referencing and single-cell references.

UPDATE and UPSERT can be specified for individual rules as well. When either UPDATE or UPSERT is specified for a specific rule, it takes precedence over the option specified in the RULES clause.

Note

If an UPSERT ALL, UPSERT, or UPDATE rule does not contain the appropriate predicates, then the database may implicitly convert it to a different type of rule:

- If an UPSERT rule contains an existential predicate, then the rule is treated as an UPDATE rule.
- An UPSERT ALL rule must have at least one existential predicate and one qualified predicate on its left side. If it has no existential predicate, then it is treated as an UPSERT rule. If it has no qualified predicate, then it is treated as an UPDATE rule

UPDATE

When you specify UPDATE, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array. If the cells do not exist, then the assignment is ignored.

AUTOMATIC ORDER

When you specify AUTOMATIC ORDER, the database evaluates the rules based on their dependency order. In this case, a cell can be assigned a value once only.

SEQUENTIAL ORDER

When you specify SEQUENTIAL ORDER, the database evaluates the rules in the order they appear. In this case, a cell can be assigned a value more than once. SEQUENTIAL ORDER is the default.

ITERATE ... [UNTIL]

Use ITERATE ... [UNTIL] to specify the number of times to cycle through the rules and, optionally, an early termination condition. The parentheses around the UNTIL condition are optional.

When you specify ITERATE ... [UNTIL], rules are evaluated in the order in which they appear. The database returns an error if both AUTOMATIC ORDER and ITERATE ... [UNTIL] are specified in the *model_rules_clause*.

cell_assignment

The *cell_assignment* clause, which is the left-hand side of the rule, specifies one or more cells to be updated. When a *cell_assignment* references a single cell, it is called a **single-cell reference**. When more than one cell is referenced, it is called a **multiple-cell reference**.

All dimension columns defined in the *model_clause* must be qualified in the *cell_assignment* clause. A dimension can be qualified using either symbolic or positional referencing.

A **symbolic reference** qualifies a single dimension column using a Boolean condition like *dimension_column=constant*. A **positional reference** is one where the dimension column is implied by its position in the DIMENSION BY clause. The only difference between symbolic references and positional references is in the treatment of nulls.

Using a single-cell symbolic reference such as `a[x=null,y=2000]`, no cells qualify because `x=null` evaluates to FALSE. However, using a single-cell positional reference such as `a[null,2000]`, a cell where `x` is null and `y` is 2000 qualifies because `null = null` evaluates to TRUE. With single-cell positional referencing, you can reference, update, and insert cells where dimension columns are null.

You can specify a condition or an expression representing a dimension column value using either symbolic or positional referencing. *condition* cannot contain aggregate functions or the CV function, and *condition* must reference a single dimension column. *expr* cannot contain a subquery. Refer to "[Model Expressions](#)" for information on model expressions.

single_column_for_loop

The *single_column_for_loop* clause lets you specify a range of cells to be updated within a single dimension column.

The IN clause lets you specify the values of the dimension column as either a list of values or as a subquery. When using *subquery*, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the WITH clause

The FROM clause lets you specify a range of values for a dimension column with discrete increments within the range. The FROM clause can only be used for those columns with a data type for which addition and subtraction is supported. The INCREMENT and DECREMENT values must be positive.

Optionally, you can specify the LIKE clause within the FROM clause. In the LIKE clause, *pattern* is a character string containing a single pattern-matching character %. This character is replaced during execution with the current incremented or decremented value in the FROM clause.

If all dimensions other than those used by a FOR loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by FOR loops is counted as part of the 10,000 row limit of the MODEL clause.

multi_column_for_loop

The *multi_column_for_loop* clause lets you specify a range of cells to be updated across multiple dimension columns. The IN clause lets you specify the values of the dimension columns as either multiple lists of values or as a subquery. When using *subquery*, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the WITH clause

If all dimensions other than those used by a FOR loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by FOR loops is counted as part of the 10,000 row limit of the MODEL clause.

① See Also

Oracle AI Database Data Warehousing Guide for more information about using FOR loops in the MODEL clause

order_by_clause

Use the ORDER BY clause to specify the order in which cells on the left-hand side of the rule are to be evaluated. The *expr* must resolve to a dimension or measure column. If the ORDER BY

clause is not specified, then the order defaults to the order of the columns as specified in the DIMENSION BY clause. See [order_by_clause](#) for more information.

Restrictions on the *order_by_clause*

Use of the ORDER BY clause in the model rule is subject to the following restrictions:

- You cannot specify SIBLINGS, *position*, or *c_alias* in the *order_by_clause* of the *model_clause*.
- You cannot specify this clause on the left-hand side of the model rule and also specify a FOR loop on the right-hand side of the rule.

expr

Specify an expression representing the value or values of the cell or cells specified on the right-hand side of the rule. *expr* cannot contain a subquery. Refer to "[Model Expressions](#)" for information on model expressions.

return_rows_clause

The *return_rows_clause* lets you specify whether to return all rows selected or only those rows updated by the model rules. ALL is the default.

reference_model

Use the *reference_model* clause when you need to access multiple arrays from inside the *model_clause*. This clause defines a read-only multidimensional array based on the results of a query.

The subclauses of the *reference_model* clause have the same semantics as for the *main_model* clause. Refer to [model_column_clauses](#) and [cell_reference_options](#).

Restrictions on the *reference_model* Clause

This clause is subject to the following restrictions:

- PARTITION BY columns cannot be specified for reference models.
- The subquery of the reference model cannot refer to columns in an outer subquery.

Set Operators: (UNION, INTERSECT, MINUS, EXCEPT) ALL

The set operators combine the rows returned by two SELECT statements into a single result. The number and data types of the columns selected by each component query must be the same, but the column lengths can be different. The names of the columns in the result set are the names of the expressions in the select list preceding the set operator.

If you combine more than two queries with set operators, then the database evaluates adjacent queries from left to right. The parentheses around the subquery are optional. You can use them to specify a different order of evaluation.

Refer to "[The Set Operators](#)" for information on these operators, including restrictions on their use.

order_by_clause

Use the ORDER BY clause to order rows returned by the statement. Without an *order_by_clause*, no guarantee exists that the same query executed more than once will retrieve rows in the same order.

SIBLINGS

The SIBLINGS keyword is valid only if you also specify the *hierarchical_query_clause* (CONNECT BY). ORDER SIBLINGS BY preserves any ordering specified in the hierarchical query clause and then applies the *order_by_clause* to the siblings of the hierarchy.

expr

expr orders rows based on their value for *expr*. The expression is based on columns in the select list or columns in the tables, views, or materialized views in the FROM clause.

position

Specify *position* to order rows based on their value for the expression in this position of the select list. The *position* value must be an integer.

You can specify multiple expressions in the *order_by_clause*. The database first sorts rows based on their values for the first expression. Rows with the same value for the first expression are then sorted based on their values for the second expression, and so on. The database sorts nulls following all others in ascending order and preceding all others in descending order. Refer to "[Sorting Query Results](#)" for a discussion of ordering query results.

ASC | DESC

Specify whether the ordering sequence is ascending or descending. ASC is the default.

NULLS FIRST | NULLS LAST

Specify whether returned rows containing null values should appear first or last in the ordering sequence.

NULLS LAST is the default for ascending order, and NULLS FIRST is the default for descending order.

Restrictions on the ORDER BY Clause

The following restrictions apply to the ORDER BY clause:

- If you have specified the DISTINCT operator in this statement, then this clause cannot refer to columns unless they appear in the select list.
- An *order_by_clause* can contain no more than 255 expressions.
- You cannot order by a LOB, LONG, or LONG RAW column, nested table, or varray.
- If you specify a [group by clause](#) in the same statement, then this *order_by_clause* is restricted to the following expressions:
 - Constants
 - Aggregate functions
 - Analytic functions
 - The functions USER, UID, and SYSDATE
 - Expressions identical to those in the *group_by_clause*
 - Expressions comprising the preceding expressions that evaluate to the same value for all rows in a group

① See Also

- ["Using the ORDER BY Clause: Examples"](#)
- [Restrictions for Linguistic Collations](#) for information on implications of how ORDER BY character values are compared linguistically
- Appendix C in *Oracle AI Database Globalization Support Guide* for the collation determination rules for the expressions in the ORDER BY clause

window_clause

Oracle Database Release 21c supports the *window_clause* in the *query_block* clause.

Rules

- If you use a new *window_specification* to specify an *existing_window_name* then
 - *existing_window_name* must refer to an earlier entry in the *window_name* list
 - You cannot use *existing_window_name* with *windowing_clause*
 - You cannot define a new window with the *query_partition_clause*. If *existing_window_name* has *order_by_clause*, then the new window definition cannot have *order_by_clause*.
- Note that OVER *window_name* is not equivalent to OVER (*window_name* ...). OVER (*window_name* ...) implies copying and modifying the window specification, and will be rejected if the referenced window specification includes a *windowing_clause*.

Example

The following query shows the usage of *window_clause* specified as part of table expression and window functions specified using the window name as defined in window clause.

```
SELECT
    ename, mgr,
    FIRST_VALUE(sal) OVER w AS "first",
    LAST_VALUE(sal) OVER w AS "last",
    NTH_VALUE(sal, 2) OVER w AS "second",
    NTH_VALUE(sal, 4) OVER w AS "fourth"
FROM emp
WINDOW w AS (PARTITION BY deptno ORDER BY sal ROWS UNBOUNDED PRECEDING);
```

qualify_clause

The QUALIFY clause allows you to filter anything that can legally appear in the SELECT expression list or in the condition that is specified within the QUALIFY clause. The expression list includes aggregate functions, columns, and analytic functions.

You can use QUALIFY to filter output of analytic functions in a single query block.

The relationship between the QUALIFY clause and analytic functions is analogous to the relationship between the HAVING clause and the GROUP BY clause.

- The QUALIFY clause must appear before the ORDER BY and FETCH FIRST clauses, but after the WINDOW clause of a SELECT statement.
- All WHERE, GROUP BY, HAVING clauses and analytic functions are completed before the QUALIFY clause is processed. The order of operations is as follows: FROM -> WHERE -> GROUP BY -> HAVING -> WINDOW -> QUALIFY -> DISTINCT -> ORDER BY -> FETCH FIRST.

Restriction

You cannot use *qualify_clause* with MODEL clause.

row_limiting_clause

The *row_limiting_clause* allows you to limit the rows returned by the query. You can specify an offset, and the number of rows or percentage of rows to return. You can use this clause to implement top-N reporting. For consistent results, specify the *order_by_clause* to ensure a deterministic sort order.

OFFSET

Use this clause to specify the number of rows to skip before row limiting begins. *offset* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *offset* is treated as 0. If you specify NULL, or a number greater than or equal to the number of rows returned by the query, then 0 rows are returned. If *offset* includes a fraction, then the fractional portion is truncated. If you do not specify this clause, then *offset* is 0 and row limiting begins with the first row.

Restrictions

This clause is subject to the following restrictions:

- You cannot specify this clause with the *for_update_clause*.
- If you specify this clause, then the select list cannot contain the sequence pseudocolumns CURRVAL or NEXTVAL.
- Materialized views are not eligible for an incremental refresh if the defining query contains the *row_limiting_clause*.
- If the select list contains columns with identical names and you specify the *row_limiting_clause*, then an ORA-00918 error occurs. This error occurs whether the identically named columns are in the same table or in different tables. You can work around this issue by specifying unique column aliases for the identically named columns.

fetch_clause

Use this clause to specify the number of rows or percentage of rows to return. If you do not specify this clause, then all rows are returned, beginning at row *offset* + 1.

APPROX | APPROXIMATE | EXACT

Specify EXACT to limit results as specified exactly.

Specify APPROX or APPROXIMATE to perform approximate vector search.

The two keywords APPROX and APPROXIMATE are synonyms. If you specify neither of them, the default is APPROXIMATE. However, approximate vector search can only be performed when all syntax and semantic rules are satisfied, the corresponding vector index is available, and the query optimizer determines to perform it. If any of these conditions are unmet, then an approximate search is not performed. In this case the query returns exact results.

Syntax and Semantic Rules for an Approximate Vector Search

- *row_limiting_partition_clause* must not be specified.
- OFFSET must not be specified.
- *percent* PERCENT (of *row_specification*, not *accuracy* PERCENT of *accuracy_clause*) must not be specified.

- `WITH TIES` must not be specified .
- The approximate row limiting clause must be associated with an `ORDER BY` clause.
- The first key of the `ORDER BY` must be a distance function (`VECTOR_DISTANCE` or variant), which must have one and only one vector column operand.
- There may be additional `ORDER BY` expressions after the distance function, but not before.

FIRST | NEXT

These keywords can be used interchangeably and are provided for semantic clarity.

row_limiting_partition_clause

You can specify one or more levels of partitions in *partition_count* to apply row limiting within each partition or each combination of all levels of partitions.

You cannot use this clause with `OFFSET`, *percent* `PERCENT`, or `WITH TIES`.

You may specify unlimited levels of partitions. For each partition level, the following rules apply:

- *partition_countX* must be a number or an expression that evaluates to a numeric value. It can be given as a constant literal, a bind, a non-scalar subquery, or a correlated variable. Otherwise an error is raised.
- If a negative number is specified, then it is treated as 0.
- If *partition_countX* is greater than the number of partitions available in this level, then certain rows from all available partitions in this level are returned.
- If *partition_countX* includes a fraction, then the fractional portion is truncated.
- If *partition_countX* in any level is `NULL`, then 0 rows are returned.
- *partition_by_exprX* must be constants, columns, nonanalytic functions, function expressions, or expressions involving any of these.

Given that the query result may be sorted in certain order, partitioned row limiting clause filters out records so that only records that meet the following conditions are returned:

- the record has *partition_by_expr1* being one of the top *partition_count1* values of *partition_by_expr1*
- within the same *partition_by_expr1*, the record has *partition_by_expr2* being one of the top *partition_count2* values of *partition_by_expr2*
- within the same *partition_by_expr1* and *partition_by_expr2*, the record has *partition_by_expr3* being one of the top *partition_count3* values of *partition_by_expr3*
- the same logic applies to all levels of partitions
- within the nested partition of *partition_by_expr1*, ..., *partition_by_exprN*, the record is the top *rowcount* rows.

The keywords `PARTITION BY` or `PARTITIONS BY` are optional as long as there is no semantic ambiguity when they are missing.

row_specification

rowcount | *percent* `PERCENT`

Use *rowcount* to specify the number of rows to return. *rowcount* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *rowcount* is treated as 0. If *rowcount* is greater than the number of rows available beginning at row

offset + 1, then all available rows are returned. If *rowcount* includes a fraction, then the fractional portion is truncated. If *rowcount* is NULL, then 0 rows are returned.

Use *percent* PERCENT to specify the percentage of the total number of selected rows to return. *percent* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *percent* is treated as 0. If *percent* is NULL, then 0 rows are returned.

If you do not specify *rowcount* or *percent* PERCENT, then 1 row is returned.

ROW | ROWS

Specify one of ROW or ROWS. These keywords can be used interchangeably and are provided for semantic clarity.

If any of these conditions are not met, an exact search will be performed even though the APPROXIMATE syntax is used. In addition, even if all the conditions are met, the optimizer may employ other cost-based decisions and choose not to use the index and perform exact search .

Example: Vector Search Query

```
SELECT docID FROM vec_table
ORDER BY VECTOR_DISTANCE(data, :query_vec)
FETCH APPROX FIRST 20 ROWS ONLY;
```

You can use this clause in vector and non-vector contexts. See examples [Partitioned Row Limiting in Non-Vector Context: Example](#) and [Partitioned Row Limiting in a Multi-Vector Search: Example](#) .

ONLY | WITH TIES

Specify ONLY to return exactly the specified number of rows or percentage of rows.

Specify WITH TIES to return additional rows with the same sort key as the last row fetched. WITH TIES must be specified with *order_by_clause* . If you do not specify the *order_by_clause*, then no additional rows will be returned.

You cannot use WITH TIES for approximate vector search and partition row limit. If you specify it, approximate search will not happen, or if there are partitions, the statement will fail.

See Also

["Row Limiting: Examples"](#)

accuracy_clause

Specify a value or certain parameters to tune the accuracy of the approximate vector search. If approximate vector search is not performed for any reason, this clause is ignored.

Rules

- Keywords WITH, TARGET, and PERCENT are optional and used for semantic clarity. There is no impact on the query's semantic if you choose not to specify these keywords.
- accuracy* must be a number or an expression that evaluates to a numeric value between 1 and 100.

- In the case where a vector index is used, the accuracy, if specified, overwrites the index specification, otherwise it inherits the index specification. In the case where no vector index is used, exact results are returned, and the accuracy is meaningless.
- PARAMETERS *efs* and *nprobes* must be a number or an expression that evaluates to a numeric value.

for_update_clause

The FOR UPDATE clause lets you lock the selected rows so that other users cannot lock or update the rows until you end your transaction. You can specify this clause only in a top-level SELECT statement, not in subqueries.

Note

Prior to updating a LOB value, you must lock the row containing the LOB. One way to lock the row is with an embedded SELECT ... FOR UPDATE statement. You can do this using one of the programmatic languages or DBMS_LOB package. For more information on lock rows before writing to a LOB, see *Oracle AI Database SecureFiles and Large Objects Developer's Guide*.

Nested table rows are not locked as a result of locking the parent table rows. If you want the nested table rows to be locked, then you must lock them explicitly.

Restrictions on the FOR UPDATE Clause

This clause is subject to the following restrictions:

- You cannot specify this clause with the following other constructs: the DISTINCT operator, CURSOR expression, set operators, *group_by_clause*, or aggregate functions.
- The tables locked by this clause must all be located on the same database and on the same database as any LONG columns and sequences referenced in the same statement.

See Also

["Using the FOR UPDATE Clause: Examples"](#)

Using the FOR UPDATE Clause on Views

In general, this clause is not supported on views. However, in some cases, a SELECT ... FOR UPDATE query on a view can succeed without any errors. This occurs when the view has been merged to its containing query block internally by the query optimizer, and SELECT ... FOR UPDATE succeeds on the internally transformed query. The examples in this section illustrate when using the FOR UPDATE clause on a view can succeed or fail.

- Using the FOR UPDATE clause on merged views

An error can occur when you use the FOR UPDATE clause on a merged view if both of the following conditions apply:

- The underlying column of the view is an expression
- The FOR UPDATE clause applies to a column list

The following statement succeeds because the underlying column of the view is not an expression:

```
SELECT employee_id FROM (SELECT * FROM employees)
FOR UPDATE OF employee_id;
```

The following statement succeeds because, while the underlying column of the view is an expression, the FOR UPDATE clause does not apply to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees)
FOR UPDATE;
```

The following statement fails because the underlying column of the view is an expression and the FOR UPDATE clause applies to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees)
FOR UPDATE OF employee_id;
*
```

Error at line 2:

ORA-01733: virtual column not allowed here

- Using the FOR UPDATE clause on non-merged views

Since the FOR UPDATE clause is not supported on views, anything that prevents view merging, such as the NO_MERGE hint, parameters that disallow view merging, or something in the query structure that prevents view merging, will result in an ORA-02014 error.

In the following example, the GROUP BY statement prevents view merging, which causes an error:

```
SELECT avgsal
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
FOR UPDATE;
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
*
```

ERROR at line 2:

ORA-02014: cannot select FOR UPDATE from view with DISTINCT, GROUP BY, etc.

Note

Due to the complexity of the view merging mechanism, Oracle recommends against using the FOR UPDATE clause on views.

OF ... *column*

Use the OF ... *column* clause to lock the select rows only for a particular table or view in a join. The columns in the OF clause only indicate which table or view rows are locked. The specific columns that you specify are not significant. However, you must specify an actual column name, not a column alias. If you omit this clause, then the database locks the selected rows from all the tables in the query.

wait clause

The NOWAIT and WAIT clauses let you tell the database how to proceed if a transaction attempts to lock a row that is locked by another transaction.

Specify NOWAIT to rollback the DML statement immediately, if a lock exists.

Specify WAIT to instruct the database to wait *integer* SECONDS , MILLISECONDS, or MICROSECONDS. Seconds is the default.

Specify `WAIT FOREVER` to instruct the database to retain its default behavior of waiting for row locks indefinitely.

If you specify neither `WAIT` nor `NOWAIT`, then the database waits until the row is available and then returns the results of the `SELECT` statement.

SKIP LOCKED

`SKIP LOCKED` is an alternative way to handle a contending transaction that is locking some rows of interest. Specify `SKIP LOCKED` to instruct the database to attempt to lock the rows specified by the `WHERE` clause and to skip any rows that are found to be already locked by another transaction. This feature is designed for use in multiconsumer queue environments. It enables queue consumers to skip rows that are locked by other consumers and obtain unlocked rows without waiting for the other consumers to finish. Refer to *Oracle AI Database Transactional Event Queues and Advanced Queuing User's Guide* for more information.

Note on the WAIT and SKIP LOCKED Clauses

If you specify `WAIT` or `SKIP LOCKED` and the table is locked in exclusive mode, then the database will not return the results of the `SELECT` statement until the lock on the table is released. In the case of `WAIT`, the `SELECT FOR UPDATE` clause is blocked regardless of the wait time specified.

row_pattern_clause

The `MATCH_RECOGNIZE` clause lets you perform pattern matching. Use this clause to recognize patterns in a sequence of rows in *table*, which is called the row pattern input table. The result of a query that uses the `MATCH_RECOGNIZE` clause is called the row pattern output table.

The `MATCH_RECOGNIZE` enables you to do the following tasks:

- Logically partition and order the data with the `PARTITION BY` and `ORDER BY` clauses.
- Define measures, which are expressions usable in other parts of the SQL query, in the `MEASURES` clause.
- Define patterns of rows to seek using the `PATTERN` clause. These patterns use regular expression syntax, a powerful and expressive feature, applied to the pattern variables you define.
- Specify the logical conditions required to map a row to a row pattern variable in the `DEFINE` clause.

① See Also

- *Oracle AI Database Data Warehousing Guide* for more information on pattern matching
- ["Row Pattern Matching: Example"](#)

row_pattern_partition_by

Specify `PARTITION BY` to divide the rows in the row pattern input table into logical groups called row pattern partitions. Use *column* to specify one or more partitioning columns. Each partition consists of the set of rows in the row pattern input table that have the same value(s) on the partitioning column(s).

If you specify this clause, then matches are found within partitions and do not cross partition boundaries. If you do not specify this clause, then all rows of the row input table constitute a single row pattern partition.

row_pattern_order_by

Specify ORDER BY to order rows within each row pattern partition. Use *column* to specify one or more ordering columns. If you specify multiple columns, then the database first sorts rows based on their values for the first column. Rows with the same value for the first column are then sorted based on their values for the second column, and so on. The database sorts nulls following all others in ascending order.

If you do not specify this clause, then the result of the *row_pattern_clause* is nondeterministic and you may get inconsistent results each time you run the query.

row_pattern_measures

Use the MEASURES clause to define one or more row pattern measure columns. These columns are included in the row pattern output table and contain values that are useful for analyzing data.

When you define a row pattern measure column, using the *row_pattern_measure_column* clause, you specify its pattern measure expression. The values in the column are calculated by evaluating the pattern measure expression whenever a match is found.

row_pattern_measure_column

Use this clause to define a row pattern measure column.

- For *expr*, specify the pattern measure expression. A pattern measure expression is an expression as described in [Expressions](#) that can contain only the following elements:
 - Constants: Text literals and numeric literals
 - References to any column of the row pattern input table
 - The CLASSIFIER function, which returns the name of the primary row pattern variable to which the row is mapped. Refer to [row_pattern_classifier_func](#) for more information.
 - The MATCH_NUMBER function, which returns the sequential number of a row pattern match within the row pattern partition. Refer to [row_pattern_match_num_func](#) for more information.
 - Row pattern navigation functions: PREV, NEXT, FIRST, and LAST. Refer to [row_pattern_navigation_func](#) for more information.
 - Row pattern aggregate functions: [AVG](#), [COUNT](#), [MAX](#), [MIN](#), or [SUM](#). Refer to [row_pattern_aggregate_func](#) for more information.
- For *c_alias*, specify the alias for the pattern measure expression. The database uses this alias in the column heading of the row pattern output table. The AS keyword is optional. The alias can be used in other parts of the query, such as the SELECT ... ORDER BY clause.

row_pattern_rows_per_match

This clause lets you specify whether the row pattern output table includes summary or detailed data about each match.

- If you specify ONE ROW PER MATCH, then each match produces one summary row. This is the default.
- If you specify ALL ROWS PER MATCH, then each match that spans multiple rows will produce one output row for each row in the match.

row_pattern_skip_to

This clause lets you specify the point to resume row pattern matching after a non-empty match is found.

- Specify `AFTER MATCH SKIP TO NEXT ROW` to resume pattern matching at the row after the first row of the current match.
- Specify `AFTER MATCH SKIP PAST LAST ROW` to resume pattern matching at the next row after the last row of the current match. This is the default.
- Specify `AFTER MATCH SKIP TO FIRST variable_name` to resume pattern matching at the first row that is mapped to pattern variable *variable_name*. The *variable_name* must be defined in the `DEFINE` clause.
- Specify `AFTER MATCH SKIP TO LAST variable_name` to resume pattern matching at the last row that is mapped to pattern variable *variable_name*. The *variable_name* must be defined in the `DEFINE` clause.
- `AFTER MATCH SKIP TO variable_name` has the same behavior as `AFTER MATCH SKIP TO LAST variable_name`.

Oracle AI Database Data Warehousing Guide for more information on the `AFTER MATCH SKIP` clauses

PATTERN

Use the `PATTERN` clause to define which pattern variables must be matched, the sequence in which they must be matched, and the quantity of rows that must be matched for each pattern variable.

A row pattern match consists of a set of contiguous rows in a row pattern partition. Each row of the match is mapped to a pattern variable. The mapping of rows to pattern variables must conform to the regular expression specified in the *row_pattern* clause, and all conditions in the `DEFINE` clause must be true.

① Note

It is outside the scope of this document to explain regular expression concepts and details. If you are not familiar with regular expressions, then you are encouraged to familiarize yourself with the topic using other sources.

The precedence of the elements that you specify in the regular expression of the `PATTERNS` clause, in decreasing order, is as follows:

- Row pattern elements (specified in the *row_pattern_primary* clause)
- Row pattern quantifiers (specified in the *row_pattern_quantifier* clause)
- Concatenation (specified in the *row_pattern_term* clause)
- Alternation (specified in the *row_pattern* clause)

① See Also

Oracle AI Database Data Warehousing Guide for more information on the PATTERN clause

row_pattern

Use this clause to specify the row pattern. A row pattern is a regular expression that can take one of the following forms:

- A single row pattern term
For example: PATTERN(A)
- A row pattern, a vertical bar, and a row pattern term
For example: PATTERN(A|B)
- A recursively built row pattern, a vertical bar, and a row pattern term
For example: PATTERN(A|B|C)

The vertical bar in this clause represents **alternation**. Alternation matches a single regular expression from a list of several possible regular expressions. Alternatives are preferred in the order they are specified. For example, if you specify PATTERN(A|B|C), then the database attempts to match A first. If A is not matched, then it attempts to match B. If B is not matched, then it attempts to match C.

row_pattern_term

This clause lets you specify a row pattern term. A row pattern term can take one of the following forms:

- A single row pattern factor
For example: PATTERN(A)
- A row pattern term followed by a row pattern factor.
For example: PATTERN(A B)
- A recursively built row pattern term followed by a row pattern factor
For example: PATTERN(A B C)

The syntax used in the second and third examples represents **concatenation**. Concatenation is used to list two or more items in a pattern to be matched and the order in which they are to be matched. For example, if you specify PATTERN(A B C), then the database first matches A, then uses the resulting matched rows to match B, then uses the resulting matched rows to match C. Only rows that match A, B, and C, are included in the row pattern match.

row_pattern_factor

This clause lets you specify a row pattern factor. A row pattern factor consists of a row pattern element, specified using the *row_pattern_primary* clause, and an optional row pattern quantifier, specified using the *row_pattern_quantifier* clause.

row_pattern_primary

Use this clause to specify the row pattern element. [Table 19-1](#) lists the valid row pattern elements and their descriptions.

Table 19-1 Row Pattern Elements

Row Pattern Element	Description
<i>variable_name</i>	Specify a primary pattern variable name that is defined in the <i>row_pattern_definition</i> clause. You cannot specify a union pattern variable that is defined in the <i>row_pattern_subset_item</i> clause.
\$	\$ matches the position after the last row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows.
^	^ matches the position before the first row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows
([<i>row_pattern</i>])	Use <i>row_pattern</i> to specify the row pattern to be matched. An empty pattern () matches an empty set of rows.
{- <i>row_pattern</i> -}	Exclusion syntax. Use <i>row_pattern</i> to specify parts of the pattern to be excluded from the output of ALL ROWS PER MATCH.
<i>row_pattern_permute</i>	Use <i>row_pattern_permute</i> to specify a pattern that is a permutation of row pattern elements. Refer to row_pattern_permute for the full semantics of this clause.

row_pattern_permute

Use the PERMUTE clause to express a pattern that is a permutation of the specified row pattern elements. For example, PATTERN (PERMUTE (A, B, C)) is equivalent to an alternation of all permutations of the three row pattern elements A, B, and C, similar to the following:

```
PATTERN (A B C | A C B | B A C | B C A | C A B | C B A)
```

Note that the row pattern elements are expanded lexicographically and that each element to permute must be separated by a comma from the other elements.

① See Also

Oracle AI Database Data Warehousing Guide for more information on permutations

row_pattern_quantifier

Use this clause to specify the row pattern quantifier, which is a postfix operator that defines the number of iterations accepted for a match.

Row pattern quantifiers are referred to as greedy; they will attempt to match as many instances of the regular expression on which they are applied as possible. The exception is row pattern quantifiers that have a question mark (?) as a suffix, which are referred to as reluctant. They will attempt to match as few instances as possible of the regular expression on which they are applied.

[Table 19-2](#) lists the valid row pattern quantifiers and the number of iterations they accept for a match. In this table, *n* and *m* represent unsigned integers.

Table 19-2 Row Pattern Quantifiers

Row Pattern Quantifier	Number of Iterations Accepted for a Match
*	0 or more iterations (greedy)
*?	0 or more iterations (reluctant)
+	1 or more iterations (greedy)
+?	1 or more iterations (reluctant)
?	0 or 1 iterations (greedy)
??	0 or 1 iterations (reluctant)
{ <i>n</i> ,}	<i>n</i> or more iterations, (<i>n</i> >= 0) (greedy)
{ <i>n</i> ,}?	<i>n</i> or more iterations, (<i>n</i> >= 0) (reluctant)
{ <i>n</i> , <i>m</i> }	Between <i>n</i> and <i>m</i> iterations, inclusive, (0 <= <i>n</i> <= <i>m</i> , 0 < <i>m</i>) (greedy)
{ <i>n</i> , <i>m</i> }?	Between <i>n</i> and <i>m</i> iterations, inclusive, (0 <= <i>n</i> <= <i>m</i> , 0 < <i>m</i>) (reluctant)
{, <i>m</i> }	Between 0 and <i>m</i> iterations, inclusive (<i>m</i> > 0) (greedy)
{, <i>m</i> }?	Between 0 and <i>m</i> iterations, inclusive (<i>m</i> > 0) (reluctant)
{ <i>n</i> }?	<i>n</i> iterations, (<i>n</i> > 0)

Oracle AI Database Data Warehousing Guide for more information on row pattern quantifiers

row_pattern_subset_clause

The SUBSET clause lets you specify one or more union row pattern variables. Use the *row_pattern_subset_item* clause to declare each union row pattern variable.

You can specify union row pattern variables in the following clauses:

- MEASURES clause: In the expression for a row pattern measure column. That is, in expression *expr* of the *row_pattern_measure_column* clause.
- DEFINE clause: In the condition that defines a primary pattern variable. That is, in *condition* of the *row_pattern_definition* clause

row_pattern_subset_item

This clause lets you create a grouping of multiple pattern variables that can be referred to with a variable name of its own. The variable name that refers to this grouping is called a union row pattern variable.

- For *variable_name* on the left side of the equal sign, specify the name of the union row pattern variable.
- On the right side of the equal sign, specify a comma-separated list of distinct primary row pattern variables within parentheses. This list cannot include any union row pattern variables.

① See Also

Oracle AI Database Data Warehousing Guide for more information on defining union row pattern variables

DEFINE

Use the DEFINE clause to specify one or more row pattern definitions. A row pattern definition specifies the conditions that a row must meet in order to be mapped to a specific pattern variable.

The DEFINE clause only supports running semantics.

① See Also

- *Oracle AI Database Data Warehousing Guide* for more information on the DEFINE clause
- *Oracle AI Database Data Warehousing Guide* for more information on running and final semantics

row_pattern_definition_list

This clause lets you specify one or more row pattern definitions.

row_pattern_definition

This clause lets you specify a row pattern definition, which contains the conditions that a row must meet in order to be mapped to the specified pattern variable.

- For *variable_name*, specify the name of the pattern variable.
- For *condition*, specify a condition as described in [Conditions](#), with the following extension: *condition* can contain any of the functions described by [row_pattern_navigation_func::=](#) and [row_pattern_aggregate_func::=](#).

row_pattern_rec_func

This clause comprises the following clauses, which let you specify row pattern recognition functions:

- *row_pattern_classifier_func*: Use this clause to specify the CLASSIFIER function, which returns a character string whose value is the name of the variable to which the row is mapped.
- *row_pattern_match_num_func*: Use this clause to specify the MATCH_NUMBER function, which returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.
- *row_pattern_navigation_func*: Use this clause to specify functions that perform row pattern navigation operations.
- *row_pattern_aggregate_func*: Use this clause to specify an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

You can specify row pattern recognition functions in the following clauses:

- **MEASURES clause:** In the expression for a row pattern measure column. That is, in expression *expr* of the *row_pattern_measure_column* clause.
- **DEFINE clause:** In the condition that defines a primary pattern variable. That is, in *condition* of the *row_pattern_definition* clause

A row pattern recognition function may behave differently depending whether you specify it in the MEASURES or DEFINE clause. These details are explained in the semantics for each clause.

row_pattern_classifier_func

The CLASSIFIER function returns a character string whose value is the name of the variable to which the row is mapped.

- In the MEASURES clause:
 - If you specify ONE ROW PER MATCH, then the query uses the last row of the match when processing the MEASURES clause, so the CLASSIFIER function returns the name of the pattern variable to which the last row of the match is mapped.
 - If you specify ALL ROWS PER MATCH, then for each row of the match found, the CLASSIFIER function returns the name of the pattern variable to which the row is mapped.

For empty matches—that is, matches that contain no rows, the CLASSIFIER function returns NULL.

- In the DEFINE clause, the CLASSIFIER function returns the name of the primary pattern variable to which the current row is mapped.

row_pattern_match_num_func

The MATCH_NUMBER function returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.

Matches within a row pattern partition are numbered sequentially starting with 1 in the order in which they are found. If multiple rows satisfy a match, then they are all assigned the same match number. Note that match numbering starts over again at 1 in each row pattern partition, because there is no inherent ordering between row pattern partitions.

- In the MEASURES clause: You can use MATCH_NUMBER to obtain the sequential number of the match within the row pattern.
- In the DEFINE clause: You can use MATCH_NUMBER to define conditions that depend upon the match number.

row_pattern_navigation_func

This clause lets you perform the following row pattern navigation operations:

- Navigate among the group of rows mapped to a pattern variable using the FIRST and LAST functions of the *row_pattern_nav_logical* clause.
- Navigate among all rows in a row pattern partition using the PREV and NEXT functions of the *row_pattern_nav_physical* clause
- Nest the FIRST or LAST function within the PREV or NEXT function using the *row_pattern_nav_compound* clause.

row_pattern_nav_logical

This clause lets you use the FIRST and LAST functions to navigate among the group of rows mapped to a pattern variable using an optional logical offset.

- The FIRST function returns the value of expression *expr* when evaluated in the first row of the group of rows mapped to the pattern variable that is specified in *expr*. If no rows are mapped to the pattern variable, then the FIRST function returns NULL.
- The LAST function returns the value of expression *expr* when evaluated in the last row of the group of rows mapped to the pattern variable that is specified in *expr*. If no rows are mapped to the pattern variable, then the LAST function returns NULL.
- Use *expr* to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional *offset* to specify the logical offset within the set of rows mapped to the pattern variable. When specified with the FIRST function, the offset is the number of rows from the first row, in ascending order. When specified with the LAST function, the offset is the number of rows from the last row in descending order. The default offset is 0.

For *offset*, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

If you specify an *offset* that is greater than or equal to the number of rows mapped to the pattern variable minus 1, then the function returns NULL.

You can specify running or final semantics for the FIRST and LAST functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
- The DEFINE clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit RUNNING. You cannot specify FINAL.

See Also

- *Oracle AI Database Data Warehousing Guide* for more information on the FIRST and LAST functions
- *Oracle AI Database Data Warehousing Guide* for more information on running and final semantics

row_pattern_nav_physical

This clause lets you use the PREV and NEXT functions to navigate all rows in a row pattern partition using an optional physical offset.

- The PREV function returns the value of expression *expr* when evaluated in the previous row in the partition. If there is no previous row in the partition, then the PREV function returns NULL.
- The NEXT function returns the value of expression *expr* when evaluated in the next row in the partition. If there is no next row in the partition, then the NEXT function returns NULL.
- Use *expr* to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional *offset* to specify the physical offset within the partition. When specified with the PREV function, it is the number of rows before the current row. When specified with the NEXT function, it is the number of rows after the current row. The default is 1. If you specify an offset of 0, then the current row is evaluated.

For *offset*, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

The PREV and NEXT functions always use running semantics. Therefore, you cannot specify the RUNNING or FINAL keywords with this clause.

① See Also

- *Oracle AI Database Data Warehousing Guide* for more information on the PREV and NEXT functions
- *Oracle AI Database Data Warehousing Guide* for more information on running and final semantics

row_pattern_nav_compound

This clause lets you nest the *row_pattern_nav_logical* clause within the *row_pattern_nav_physical* clause. That is, it lets you nest the FIRST or LAST function within the PREV or NEXT function. The *row_pattern_nav_logical* clause is evaluated first and then the result is supplied to the *row_pattern_nav_physical* clause.

Refer to [row_pattern_nav_logical](#) and [row_pattern_nav_physical](#) for the full semantics of these clauses.

① See Also

Oracle AI Database Data Warehousing Guide for more information on nesting the FIRST and LAST functions within the PREV and NEXT functions

row_pattern_aggregate_func

This clause lets you use an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

For *aggregate_function*, specify any one of the [AVG](#), [COUNT](#), [MAX](#), [MIN](#), or [SUM](#) functions. The DISTINCT keyword is not supported.

You can specify running or final semantics for aggregate functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
- The DEFINE clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit RUNNING. You cannot specify FINAL.

① See Also

- *Oracle AI Database Data Warehousing Guide* for more information on aggregate functions
- *Oracle AI Database Data Warehousing Guide* for more information on running and final semantics

Examples

SQL Macros - Scalar Valued Macros: Examples

Print Hello <name>

A PL/SQL function greet is defined as a scalar SQL Macro that returns the string 'Hello, <name>!' when called from a SQL SELECT statement.

```
create or replace function greet(name varchar2 default 'World')
    return varchar2 SQL_MACRO(Scalar) is
begin
    return q'{ 'Hello, ' || name || '!' }';
end;
/
```

You can call greet in two ways:

Option 1: Without passing an explicit argument . In this case the default argument is used and 'Hello World' is returned.

```
SELECT greet ('World') from dual;
-----
Hello, World!
```

Option 2: Passing an explicit argument . In this case the argument passed is used and 'Hello Bob' is returned.

```
SELECT greet ('Bob') from dual;
-----
Hello, Bob!
```

Split String Based on Delimiter

The PL/SQL function split_part splits a string on the specified delimiter and returns the part at the specified position.

```
create or replace function split_part(string    varchar2,
                                     delimiter varchar2,
                                     position  pls_integer)
    return varchar2 SQL_MACRO(Scalar) is
begin
    return q'{
        regexp_substr(
            replace(string, delimiter||delimiter, delimiter||' '||delimiter),
            '^[^'||delimiter||']+', 1, position, 'imx')
    }';
end;
/
SELECT split_part( sysdate, '-', 2) month from dual;
-----
MONTH
-----
OCT
```

SQL Macros - Table Valued Macros: Examples

The macro function budget computes the amount of each department's budget for a given job. It returns the number of employees in each department with the specified job title.

```
create or replace function budget(job varchar2) return varchar2 SQL_MACRO is
begin
    return q'{
```

```

        select deptno, sum(sal) budget
        from emp
        where job = budget.job
        group by deptno
    }';
end;
/

```

```

SELECT * FROM budget ('MANAGER');
  DEPTNO      BUDGET
-----
20          2975
30          2850
10          2450

```

Using a PL/SQL Function in the WITH Clause: Examples

The following example declares and defines a PL/SQL function `get_domain` in the `WITH` clause. The `get_domain` function returns the domain name from a URL string, assuming that the URL string has the "www" prefix immediately preceding the domain name, and the domain name is separated by dots on the left and right. The `SELECT` statement uses `get_domain` to find distinct catalog domain names from the `orders` table in the `oe` schema.

```

WITH
FUNCTION get_domain(url VARCHAR2) RETURN VARCHAR2 IS
    pos BINARY_INTEGER;
    len BINARY_INTEGER;
BEGIN
    pos := INSTR(url, 'www.');
    len := INSTR(SUBSTR(url, pos + 4), '.') - 1;
    RETURN SUBSTR(url, pos + 4, len);
END;
SELECT DISTINCT get_domain(catalog_url)
FROM product_information;
/

```

Subquery Factoring: Example

The following statement creates the query names `dept_costs` and `avg_cost` for the initial query block containing a join, and then uses the query names in the body of the main query.

```

WITH
    dept_costs AS (
        SELECT department_name, SUM(salary) dept_total
        FROM employees e, departments d
        WHERE e.department_id = d.department_id
        GROUP BY department_name),
    avg_cost AS (
        SELECT SUM(dept_total)/COUNT(*) avg
        FROM dept_costs)
SELECT * FROM dept_costs
WHERE dept_total >
    (SELECT avg FROM avg_cost)
ORDER BY department_name;

```

```

DEPARTMENT_NAME      DEPT_TOTAL
-----
Sales                304500
Shipping             156400

```

Recursive Subquery Factoring: Examples

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level.

```
WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
  (
    SELECT employee_id, last_name, manager_id, 0 reportLevel
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  )
SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
ORDER BY reportLevel, eid;
```

EID	EMP_LAST	MGR_ID	REPORTLEVEL
101	Kochhar	100	0
108	Greenberg	101	1
200	Whalen	101	1
203	Mavris	101	1
204	Baer	101	1
205	Higgins	101	1
109	Faviet	108	2
110	Chen	108	2
111	Sciarra	108	2
112	Urman	108	2
113	Popp	108	2
206	Gietz	205	2

The following statement shows employees who directly or indirectly report to employee 101, their reporting level, and their management chain.

```
WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel, mgr_list) AS
  (
    SELECT employee_id, last_name, manager_id, 0 reportLevel,
           CAST(manager_id AS VARCHAR2(2000))
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1,
           CAST(mgr_list || ',' || manager_id AS VARCHAR2(2000))
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  )
SELECT eid, emp_last, mgr_id, reportLevel, mgr_list
FROM reports_to_101
ORDER BY reportLevel, eid;
```

EID	EMP_LAST	MGR_ID	REPORTLEVEL	MGR_LIST
101	Kochhar	100	0	100
108	Greenberg	101	1	100,101
200	Whalen	101	1	100,101
203	Mavris	101	1	100,101
204	Baer	101	1	100,101
205	Higgins	101	1	100,101
109	Faviet	108	2	100,101,108

110 Chen	108	2	100,101,108
111 Sciarra	108	2	100,101,108
112 Urman	108	2	100,101,108
113 Popp	108	2	100,101,108
206 Gietz	205	2	100,101,205

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level. It stops at reporting level 1.

```
WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
  (
    SELECT employee_id, last_name, manager_id, 0 reportLevel
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  )
SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
WHERE reportLevel <= 1
ORDER BY reportLevel, eid;
```

EID	EMP_LAST	MGR_ID	REPORTLEVEL
101	Kochhar	100	0
108	Greenberg	101	1
200	Whalen	101	1
203	Mavris	101	1
204	Baer	101	1
205	Higgins	101	1

The following statement shows the entire organization, indenting for each level of management.

```
WITH
  org_chart (eid, emp_last, mgr_id, reportLevel, salary, job_id) AS
  (
    SELECT employee_id, last_name, manager_id, 0 reportLevel, salary, job_id
    FROM employees
    WHERE manager_id is null
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id,
           r.reportLevel+1 reportLevel, e.salary, e.job_id
    FROM org_chart r, employees e
    WHERE r.eid = e.manager_id
  )
SEARCH DEPTH FIRST BY emp_last SET order1
SELECT lpad(' ', 2*reportLevel)||emp_last emp_name, eid, mgr_id, salary, job_id
FROM org_chart
ORDER BY order1;
```

. . .				

The following statement shows the entire organization, indenting for each level of management, with each level ordered by *hire_date*. The value of *is_cycle* is set to Y for any employee who has the same *hire_date* as any manager above him in the management chain.

```
WITH
  dup_hiredate (eid, emp_last, mgr_id, reportLevel, hire_date, job_id) AS
  (
    SELECT employee_id, last_name, manager_id, 0 reportLevel, hire_date, job_id
    FROM employees
    WHERE manager_id is null
  UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id,
           r.reportLevel+1 reportLevel, e.hire_date, e.job_id
    FROM dup_hiredate r, employees e
    WHERE r.eid = e.manager_id
  )
  SEARCH DEPTH FIRST BY hire_date SET order1
  CYCLE hire_date SET is_cycle TO 'Y' DEFAULT 'N'
SELECT lpad(' ', 2*reportLevel)||emp_last emp_name, eid, mgr_id,
       hire_date, job_id, is_cycle
FROM dup_hiredate
ORDER BY order1;
```

EMP_NAME	EID	MGR_ID	HIRE_DATE	JOB_ID	IS_CYCLE

. . .					

Analytic Views: Examples

The following statement uses the persistent analytic view `sales_av`. The query selects the `member_name` hierarchical attribute of `time_hier`, which is the alias of a hierarchy of the same name, and values from the sales and units measures of the analytic view that are dimensioned by the time attribute dimension used by the `time_hier` hierarchy.. The results of the selection are filtered to those for the YEAR level of the hierarchy. The results are returned in hierarchical order.

```

SELECT time_hier.member_name as TIME,
       sales,
       units
FROM
    sales_av HIERARCHIES(time_hier)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

```

The results of the query are the following:

TIME	SALES	UNITS
CY2011	6755115980.73	24462444
CY2012	6901682398.95	24400619
CY2013	7240938717.57	24407259
CY2014	7579746352.89	24402666
CY2015	7941102885.15	24475206

Transitory Analytic View Examples

The following statement defines the transitory analytic view `my_av` in the `WITH` clause. The transitory analytic view is based on the persistent analytic view `sales_av`. The `lag_sales` calculated measure is a LAG calculation that is used at query time.

```

WITH
    my_av ANALYTIC VIEW AS (
        USING sales_av HIERARCHIES (time_hier)

```

```

        ADD MEASURES (
            lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
        )
    )
SELECT time_hier.member_name time, sales, lag_sales
FROM my_av HIERARCHIES (time_hier)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

```

The results of the query are the following:

TIME	SALES	LAG_SALES
-----	-----	-----
CY2011	6755115981	(null)
CY2012	6901682399	6755115981
CY2013	7240938718	6901682399
CY2014	7579746353	7240938718
CY2015	7941102885	7579746353

The following statement defines a transitory analytic view that uses a filter clause.

```

WITH
  my_av ANALYTIC VIEW AS (
    USING sales_av HIERARCHIES (time_hier)
    FILTER FACT (
      time_hier TO quarter_of_year IN (1, 2)
      AND year_name IN ('CY2011', 'CY2012')
    )
  )
SELECT time_hier.member_name time, sales
FROM my_av HIERARCHIES (time_hier)
WHERE time_hier.level_name IN ('YEAR', 'QUARTER')
ORDER BY time_hier.hier_order;

```

The results of the query are the following:

TIME	SALES
-----	-----
CY2011	3340459835
Q1CY2011	1625299627
Q2CY2011	1715160208
CY2012	3397271965
Q1CY2012	1644857783
Q2CY2012	1752414182

Inline Analytic View Example

The following statement defines an inline analytic view in the FROM clause. The transitory analytic view is based on the persistent analytic view sales_av. The lag_sales calculated measure is a LAG calculation that is used at query time.

```

SELECT time_hier.member_name time, sales, lag_sales
FROM
  ANALYTIC VIEW (

```

```

        USING sales_av HIERARCHIES (time_hier)
        ADD MEASURES (
            lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
        )
    )
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;

```

The results of the query are the following:

TIME	SALES	LAG_SALES
-----	-----	-----
CY2011	6755115981	(null)
CY2012	6901682399	6755115981
CY2013	7240938718	6901682399
CY2014	7579746353	7240938718
CY2015	7941102885	7579746353

Simple Query Examples

The following statement selects rows from the employees table with the department number of 30:

```

SELECT *
  FROM employees
 WHERE department_id = 30
 ORDER BY last_name;

```

The following statement selects the name, job, salary and department number of all employees except purchasing clerks from department number 30:

```

SELECT last_name, job_id, salary, department_id
  FROM employees
 WHERE NOT (job_id = 'PU_CLERK' AND department_id = 30)
 ORDER BY last_name;

```

The following statement selects from subqueries in the FROM clause and for each department returns the total employees and salaries as a decimal value of all the departments:

```

SELECT a.department_id "Department",
       a.num_emp/b.total_count "%_Employees",
       a.sal_sum/b.total_sal "%_Salary"
  FROM
    (SELECT department_id, COUNT(*) num_emp, SUM(salary) sal_sum
      FROM employees
     GROUP BY department_id) a,
    (SELECT COUNT(*) total_count, SUM(salary) total_sal
      FROM employees) b
 ORDER BY a.department_id;

```

Selecting from a Partition: Example

You can select rows from a single partition of a partitioned table by specifying the keyword `PARTITION` in the `FROM` clause. This SQL statement assigns an alias for and retrieves rows from the `sales_q2_2000` partition of the sample table `sh.sales`:

```
SELECT * FROM sales PARTITION (sales_q2_2000) s
WHERE s.amount_sold > 1500
ORDER BY cust_id, time_id, channel_id;
```

The following example selects rows from the `oe.orders` table for orders earlier than a specified date:

```
SELECT * FROM orders
WHERE order_date < TO_DATE('2006-06-15', 'YYYY-MM-DD');
```

Selecting a Sample: Examples

The following query estimates the number of orders in the `oe.orders` table:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);

COUNT(*)*10
-----
          70
```

Because the query returns an estimate, the actual return value may differ from one query to the next.

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);

COUNT(*)*10
-----
          80
```

The following query adds a seed value to the preceding query. The database always returns the same estimate given the same seed value:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);

COUNT(*)*10
-----
        130
```

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED(4);

COUNT(*)*10
-----
        120
```

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);

COUNT(*)*10
-----
        130
```

Using Flashback Queries: Example

The following statements show a current value from the sample table `hr.employees` and then change the value. The intervals used in these examples are very short for demonstration purposes. Time intervals in your own environment are likely to be larger.

```
SELECT salary FROM employees
WHERE last_name = 'Chung';
```

```

SALARY
-----
      3800

UPDATE employees SET salary = 4000
  WHERE last_name = 'Chung';
1 row updated.

SELECT salary FROM employees
  WHERE last_name = 'Chung';

```

```

SALARY
-----
      4000

```

To learn what the value was before the update, you can use the following Flashback Query:

```

SELECT salary FROM employees
  AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' MINUTE)
  WHERE last_name = 'Chung';

```

```

SALARY
-----
      3800

```

To learn what the values were during a particular time period, you can use a version Flashback Query:

```

SELECT salary FROM employees
  VERSIONS BETWEEN TIMESTAMP
    SYSTIMESTAMP - INTERVAL '10' MINUTE AND
    SYSTIMESTAMP - INTERVAL '1' MINUTE
  WHERE last_name = 'Chung';

```

To revert to the earlier value, use the Flashback Query as the subquery of another UPDATE statement:

```

UPDATE employees SET salary =
  (SELECT salary FROM employees
   AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '2' MINUTE)
   WHERE last_name = 'Chung')
  WHERE last_name = 'Chung';
1 row updated.

SELECT salary FROM employees
  WHERE last_name = 'Chung';

```

```

SALARY
-----
      3800

```

Using the GROUP BY Clause: Examples

To return the minimum and maximum salaries for each department in the employees table, issue the following statement:

```

SELECT department_id, MIN(salary), MAX (salary)
  FROM employees
  GROUP BY department_id
  ORDER BY department_id;

```

To return the minimum and maximum salaries for the clerks in each department, issue the following statement:

```
SELECT department_id, MIN(salary), MAX (salary)
   FROM employees
   WHERE job_id = 'PU_CLERK'
   GROUP BY department_id
   ORDER BY department_id;
```

The following example counts how many employees were hired each year. The GROUP BY clause uses the column alias YEAR_HIRED, so this groups using the expression TRUNC(hire_date, 'YYYY')

```
SELECT TRUNC(hire_date, 'YYYY') year_hired, COUNT(*)
   FROM employees
   GROUP BY year_hired
   ORDER BY year_hired;
```

```
YEAR_HIRED COUNT(*)
-----
01-JAN-2011 1
01-JAN-2012 7
...
01-JAN-2017 19
01-JAN-2018 11
```

The following example counts how many employees were hired each day. The query groups by HIRE_DATE, which is the name of a column in EMPLOYEES and a SELECT list alias. The column name takes priority, so the query groups by the column, not the alias.

```
SELECT TRUNC(hire_date, 'YYYY') hire_date, COUNT(*)
   FROM employees
   GROUP BY hire_date
   ORDER BY hire_date;
```

```
HIRE_DATE COUNT(*)
-----
01-JAN-2011 1
01-JAN-2012 4
01-JAN-2012 1
...
01-JAN-2018 1
01-JAN-2018 1
```

Using the GROUP BY CUBE Clause: Example

To return the number of employees and their average yearly salary across all possible combinations of department and job category, issue the following query on the sample tables hr.employees and hr.departments:

```
SELECT DECODE(GROUPING(department_name), 1, 'All Departments',
             department_name) AS department_name,
       DECODE(GROUPING(job_id), 1, 'All Jobs', job_id) AS job_id,
       COUNT(*) "Total Empl", AVG(salary) * 12 "Average Sal"
   FROM employees e, departments d
  WHERE d.department_id = e.department_id
  GROUP BY CUBE (department_name, job_id)
  ORDER BY department_name, job_id;
```

DEPARTMENT_NAME	JOB_ID	Total Empl	Average Sal
-----------------	--------	------------	-------------

```

-----
Accounting          AC_ACCOUNT      1          99600
Accounting          AC_MGR          1         144000
Accounting          All Jobs        2         121800
Administration      AD_ASST         1          52800
. . .
Shipping            ST_CLERK        20         33420
Shipping            ST_MAN          5          87360

```

Using the GROUPING SETS Clause: Example

The following example finds the sum of sales aggregated for three precisely specified groups:

- (channel_desc, calendar_month_desc, country_id)
- (channel_desc, country_id)
- (calendar_month_desc, country_id)

Without the GROUPING SETS syntax, you would have to write less efficient queries with more complicated SQL. For example, you could run three separate queries and UNION them, or run a query with a CUBE(channel_desc, calendar_month_desc, country_id) operation and filter out five of the eight groups it would generate.

```

SELECT channel_desc, calendar_month_desc, co.country_id,
       TO_CHAR(sum(amount_sold) , '9,999,999,999') SALES$
FROM sales, customers, times, channels, countries co
WHERE sales.time_id=times.time_id
      AND sales.cust_id=customers.cust_id
      AND sales.channel_id= channels.channel_id
      AND customers.country_id = co.country_id
      AND channels.channel_desc IN ('Direct Sales', 'Internet')
      AND times.calendar_month_desc IN ('2000-09', '2000-10')
      AND co.country_iso_code IN ('UK', 'US')
GROUP BY GROUPING SETS(
    (channel_desc, calendar_month_desc, co.country_id),
    (channel_desc, co.country_id),
    (calendar_month_desc, co.country_id) );

```

```

CHANNEL_DESC      CALENDAR  COUNTRY_ID  SALES$
-----
Internet          2000-09      52790      124,224
Direct Sales      2000-09      52790      638,201
Internet          2000-10      52790      137,054
Direct Sales      2000-10      52790      682,297
                  2000-09      52790      762,425
                  2000-10      52790      819,351
Internet          52790        261,278
Direct Sales      52790      1,320,497

```

Hierarchical Query: Examples

The following query with a CONNECT BY clause defines a hierarchical relationship in which the employee_id value of the parent row is equal to the manager_id value of the child row:

```
SELECT last_name, employee_id, manager_id FROM employees
       CONNECT BY employee_id = manager_id
       ORDER BY last_name;
```

In the following CONNECT BY clause, the PRIOR operator applies only to the employee_id value. To evaluate this condition, the database evaluates employee_id values for the parent row and manager_id, salary, and commission_pct values for the child row:

```
SELECT last_name, employee_id, manager_id FROM employees
       CONNECT BY PRIOR employee_id = manager_id
       AND salary > commission_pct
       ORDER BY last_name;
```

To qualify as a child row, a row must have a manager_id value equal to the employee_id value of the parent row and it must have a salary value greater than its commission_pct value.

Using the HAVING Condition: Example

To return the minimum and maximum salaries for the employees in each department whose lowest salary is less than \$5,000, issue the next statement:

```
SELECT department_id, MIN(salary), MAX (salary)
       FROM employees
       GROUP BY department_id
       HAVING MIN(salary) < 5000
       ORDER BY department_id;
```

DEPARTMENT_ID	MIN(SALARY)	MAX(SALARY)
10	4400	4400
30	2500	11000
50	2100	8200
60	4200	9000

The following example uses a correlated subquery in a HAVING clause that eliminates from the result set any departments without managers and managers without departments:

```
SELECT department_id, manager_id
       FROM employees
       GROUP BY department_id, manager_id HAVING (department_id, manager_id) IN
       (SELECT department_id, manager_id FROM employees x
        WHERE x.department_id = employees.department_id)
       ORDER BY department_id;
```

Using the ORDER BY Clause: Examples

To select all purchasing clerk records from employees and order the results by salary in descending order, issue the following statement:

```
SELECT *
       FROM employees
       WHERE job_id = 'PU_CLERK'
       ORDER BY salary DESC;
```

To select information from employees ordered first by ascending department number and then by descending salary, issue the following statement:

```

SELECT last_name, department_id, salary
FROM employees
ORDER BY department_id ASC, salary DESC, last_name;

```

To select the same information as the previous SELECT and use the positional ORDER BY notation, issue the following statement, which orders by ascending department_id, then descending salary, and finally alphabetically by last_name:

```

SELECT last_name, department_id, salary
FROM employees
ORDER BY 2 ASC, 3 DESC, 1;

```

The MODEL clause: Examples

The view created below is based on the sample sh schema and is used by the example that follows.

```

CREATE OR REPLACE VIEW sales_view_ref AS
  SELECT country_name country,
         prod_name prod,
         calendar_year year,
         SUM(amount_sold) sale,
         COUNT(amount_sold) cnt
  FROM sales, times, customers, countries, products
 WHERE sales.time_id = times.time_id
    AND sales.prod_id = products.prod_id
    AND sales.cust_id = customers.cust_id
    AND customers.country_id = countries.country_id
    AND ( customers.country_id = 52779
        OR customers.country_id = 52776 )
    AND ( prod_name = 'Standard Mouse'
        OR prod_name = 'Mouse Pad' )
 GROUP BY country_name, prod_name, calendar_year;

SELECT country, prod, year, sale
FROM sales_view_ref
ORDER BY country, prod, year;

```

COUNTRY	PROD	YEAR	SALE
-----	-----	-----	-----
France	Mouse Pad	1998	2509.42
France	Mouse Pad	1999	3678.69
France	Mouse Pad	2000	3000.72
France	Mouse Pad	2001	3269.09
France	Standard Mouse	1998	2390.83
France	Standard Mouse	1999	2280.45
France	Standard Mouse	2000	1274.31
France	Standard Mouse	2001	2164.54
Germany	Mouse Pad	1998	5827.87
Germany	Mouse Pad	1999	8346.44
Germany	Mouse Pad	2000	7375.46
Germany	Mouse Pad	2001	9535.08
Germany	Standard Mouse	1998	7116.11
Germany	Standard Mouse	1999	6263.14
Germany	Standard Mouse	2000	2637.31
Germany	Standard Mouse	2001	6456.13

16 rows selected.

The next example creates a multidimensional array from sales_view_ref with columns containing country, product, year, and sales. It also:

- Assigns the sum of the sales of the Mouse Pad for years 1999 and 2000 to the sales of the Mouse Pad for year 2001, if a row containing sales of the Mouse Pad for year 2001 exists.
- Assigns the value of sales of the Standard Mouse for year 2001 to sales of the Standard Mouse for year 2002, creating a new row if a row containing sales of the Standard Mouse for year 2002 does not exist.

```

SELECT country,prod,year,s
FROM sales_view_ref
MODEL
  PARTITION BY (country)
  DIMENSION BY (prod, year)
  MEASURES (sale s)
  IGNORE NAV
  UNIQUE DIMENSION
  RULES UPSERT SEQUENTIAL ORDER
  (
    s[prod='Mouse Pad', year=2001] =
      s['Mouse Pad', 1999] + s['Mouse Pad', 2000],
    s['Standard Mouse', 2002] = s['Standard Mouse', 2001]
  )
ORDER BY country, prod, year;

```

COUNTRY	PROD	YEAR	SALE
France	Mouse Pad	1998	2509.42
France	Mouse Pad	1999	3678.69
France	Mouse Pad	2000	3000.72
France	Mouse Pad	2001	6679.41
France	Standard Mouse	1998	2390.83
France	Standard Mouse	1999	2280.45
France	Standard Mouse	2000	1274.31
France	Standard Mouse	2001	2164.54
France	Standard Mouse	2002	2164.54
Germany	Mouse Pad	1998	5827.87
Germany	Mouse Pad	1999	8346.44
Germany	Mouse Pad	2000	7375.46
Germany	Mouse Pad	2001	15721.9
Germany	Standard Mouse	1998	7116.11
Germany	Standard Mouse	1999	6263.14
Germany	Standard Mouse	2000	2637.31
Germany	Standard Mouse	2001	6456.13
Germany	Standard Mouse	2002	6456.13

18 rows selected.

The first rule uses UPDATE behavior because symbolic referencing is used on the left-hand side of the rule. The rows represented by the left-hand side of the rule exist, so the measure columns are updated. If the rows did not exist, then no action would have been taken.

The second rule uses UPSERT behavior because positional referencing is used on the left-hand side and a single cell is referenced. The rows do not exist, so new rows are inserted and the related measure columns are updated. If the rows did exist, then the measure columns would have been updated.

Oracle AI Database Data Warehousing Guide for an expanded discussion and examples

The next example uses the same `sales_view_ref` view and the analytic function `SUM` to calculate a cumulative sum (`csum`) of sales per country and per year.

```
SELECT country, year, sale, csum
FROM
  (SELECT country, year, SUM(sale) sale
   FROM sales_view_ref
   GROUP BY country, year
  )
MODEL DIMENSION BY (country, year)
      MEASURES (sale, 0 csum)
      RULES (csum[any, any]=
              SUM(sale) OVER (PARTITION BY country
                              ORDER BY year
                              ROWS UNBOUNDED PRECEDING)
            )
ORDER BY country, year;
```

COUNTRY	YEAR	SALE	CSUM
France	1998	4900.25	4900.25
France	1999	5959.14	10859.39
France	2000	4275.03	15134.42
France	2001	5433.63	20568.05
Germany	1998	12943.98	12943.98
Germany	1999	14609.58	27553.56
Germany	2000	10012.77	37566.33
Germany	2001	15991.21	53557.54

8 rows selected.

Row Limiting: Examples

The following statement returns the 5 employees with the lowest `employee_id` values:

```
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
FETCH FIRST 5 ROWS ONLY;
```

EMPLOYEE_ID	LAST_NAME
100	King
101	Yang
102	Garcia
103	James
104	Miller

The following statement returns the next 5 employees with the lowest `employee_id` values:

```
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
OFFSET 5 ROWS FETCH NEXT 5 ROWS ONLY;
```

EMPLOYEE_ID	LAST_NAME
105	Austin
106	Pataballa

```

107 Lorentz
108 Greenberg
109 Faviet

```

The following statement returns the 5 percent of employees with the lowest salaries:

```

SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS ONLY;

```

EMPLOYEE_ID	LAST_NAME	SALARY
132	Olson	2100
128	Markle	2200
136	Philtanker	2200
127	Landry	2400
135	Gee	2400
119	Colmenares	2500

Because WITH TIES is specified, the following statement returns the 5 percent of employees with the lowest salaries, plus all additional employees with the same salary as the last row fetched in the previous example:

```

SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS WITH TIES;

```

EMPLOYEE_ID	LAST_NAME	SALARY
132	Olson	2100
128	Markle	2200
136	Philtanker	2200
127	Landry	2400
135	Gee	2400
119	Colmenares	2500
131	Marlow	2500
140	Patel	2500
144	Vargas	2500
182	Sullivan	2500
191	Perkins	2500

Using the FOR UPDATE Clause: Examples

The following statement locks rows in the employees table with purchasing clerks located in Oxford, which has location_id 2500, and locks rows in the departments table with departments in Oxford that have purchasing clerks:

```

SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e, departments d
WHERE job_id = 'SA_REP'
AND e.department_id = d.department_id
AND location_id = 2500
ORDER BY e.employee_id
FOR UPDATE;

```

The following statement locks only those rows in the employees table with purchasing clerks located in Oxford. No rows are locked in the departments table:

```

SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e JOIN departments d

```

```

    USING (department_id)
    WHERE job_id = 'SA_REP'
    AND location_id = 2500
    ORDER BY e.employee_id
    FOR UPDATE OF e.salary;

```

Using the WITH CHECK OPTION Clause: Example

The following statement is legal even though the third value inserted violates the condition of the subquery *where_clause*:

```

INSERT INTO (SELECT department_id, department_name, location_id
    FROM departments WHERE location_id < 2000)
VALUES (9999, 'Entertainment', 2500);

```

However, the following statement is illegal because it contains the WITH CHECK OPTION clause:

```

INSERT INTO (SELECT department_id, department_name, location_id
    FROM departments WHERE location_id < 2000 WITH CHECK OPTION)
VALUES (9999, 'Entertainment', 2500);
*

```

ERROR at line 2:

ORA-01402: view WITH CHECK OPTION where-clause violation

Using PIVOT and UNPIVOT: Examples

The `oe.orders` table contains information about when an order was placed (`order_date`), how it was placed (`order_mode`), and the total amount of the order (`order_total`), as well as other information. The following example shows how to use the PIVOT clause to pivot `order_mode` values into columns, aggregating `order_total` data in the process, to get yearly totals by order mode:

```

CREATE TABLE pivot_table AS
SELECT * FROM
(SELECT EXTRACT(YEAR FROM order_date) year, order_mode, order_total FROM orders)
PIVOT
(SUM(order_total) FOR order_mode IN ('direct' AS Store, 'online' AS Internet));

SELECT * FROM pivot_table ORDER BY year;

```

YEAR	STORE	INTERNET
2004	5546.6	
2006	371895.5	100056.6
2007	1274078.8	1271019.5
2008	252108.3	393349.4

The UNPIVOT clause lets you rotate specified columns so that the input column headings are output as values of one or more descriptor columns, and the input column values are output as values of one or more measures columns. The first query that follows shows that nulls are excluded by default. The second query shows that you can include nulls using the INCLUDE NULLS clause.

```

SELECT * FROM pivot_table
UNPIVOT (yearly_total FOR order_mode IN (store AS 'direct',
    internet AS 'online'))
ORDER BY year, order_mode;

```

YEAR	ORDER_	YEARLY_TOTAL
2004	direct	5546.6
2006	direct	371895.5

2006 online	100056.6
2007 direct	1274078.8
2007 online	1271019.5
2008 direct	252108.3
2008 online	393349.4

7 rows selected.

```
SELECT * FROM pivot_table
UNPIVOT INCLUDE NULLS
(yearly_total FOR order_mode IN (store AS 'direct', internet AS 'online'))
ORDER BY year, order_mode;
```

YEAR	ORDER_	YEARLY_TOTAL
-----	-----	-----
2004	direct	5546.6
2004	online	
2006	direct	371895.5
2006	online	100056.6
2007	direct	1274078.8
2007	online	1271019.5
2008	direct	252108.3
2008	online	393349.4

8 rows selected.

Using Join Queries: Examples

The following examples show various ways of joining tables in a query. In the first example, an equijoin returns the name and job of each employee and the number and name of the department in which the employee works:

```
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
ORDER BY last_name, job_id;
```

LAST_NAME	JOB_ID	DEPARTMENT_ID	DEPARTMENT_NAME
-----	-----	-----	-----
Abel	SA_REP	80	Sales
Ande	SA_REP	80	Sales
Atkinson	ST_CLERK	50	Shipping
Austin	IT_PROG	60	IT
. . .			

You must use a join to return this data because employee names and jobs are stored in a different table than department names. The database combines rows of the two tables according to this join condition:

```
employees.department_id = departments.department_id
```

The following equijoin returns the name, job, department number, and department name of all sales managers:

```
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
AND job_id = 'SA_MAN'
ORDER BY last_name;
```

LAST_NAME	JOB_ID	DEPARTMENT_ID	DEPARTMENT_NAME
-----	-----	-----	-----

Cambrault	SA_MAN	80 Sales
Errazuriz	SA_MAN	80 Sales
Partners	SA_MAN	80 Sales
Russell	SA_MAN	80 Sales
Zlotkey	SA_MAN	80 Sales

This query is identical to the preceding example, except that it uses an additional *where_clause* condition to return only rows with a job value of 'SA_MAN'.

Using Subqueries: Examples

To determine who works in the same department as employee 'Lorentz', issue the following statement:

```
SELECT last_name, department_id FROM employees
WHERE department_id =
      (SELECT department_id FROM employees
       WHERE last_name = 'Lorentz')
ORDER BY last_name, department_id;
```

To give all employees in the employees table a 10% raise if they have changed jobs—if they appear in the job_history table—issue the following statement:

```
UPDATE employees
SET salary = salary * 1.1
WHERE employee_id IN (SELECT employee_id FROM job_history);
```

To create a second version of the departments table new_departments, with only three of the columns of the original table, issue the following statement:

```
CREATE TABLE new_departments
(department_id, department_name, location_id)
AS SELECT department_id, department_name, location_id
FROM departments;
```

Using Self Joins: Example

The following query uses a self join to return the name of each employee along with the name of the employee's manager. A WHERE clause is added to shorten the output.

```
SELECT e1.last_name||' works for '||e2.last_name
"Employees and Their Managers"
FROM employees e1, employees e2
WHERE e1.manager_id = e2.employee_id
AND e1.last_name LIKE 'R%'
ORDER BY e1.last_name;
```

Employees and Their Managers

```
-----
Rajs works for Mourgos
Raphaely works for King
Rogers works for Kaufling
Russell works for King
```

The join condition for this query uses the aliases e1 and e2 for the sample table employees:

```
e1.manager_id = e2.employee_id
```

Using Outer Joins: Examples

The following example shows how a partitioned outer join fills data gaps in rows to facilitate analytic function specification and reliable report formatting. The example first creates a small data table to be used in the join:

```

SELECT d.department_id, e.last_name
  FROM departments d LEFT OUTER JOIN employees e
    ON d.department_id = e.department_id
 ORDER BY d.department_id, e.last_name;

```

Users familiar with the traditional database outer joins syntax will recognize the same query in this form:

```

SELECT d.department_id, e.last_name
  FROM departments d, employees e
 WHERE d.department_id = e.department_id(+)
 ORDER BY d.department_id, e.last_name;

```

Oracle strongly recommends that you use the more flexible FROM clause join syntax shown in the former example.

The left outer join returns all departments, including those without any employees. The same statement with a right outer join returns all employees, including those not yet assigned to a department:

Note

The employee Zeuss was added to the employees table for these examples, and is not part of the sample data.

```

SELECT d.department_id, e.last_name
  FROM departments d RIGHT OUTER JOIN employees e
    ON d.department_id = e.department_id
 ORDER BY d.department_id, e.last_name;

```

```

DEPARTMENT_ID LAST_NAME
-----
. . .
      110 Gietz
      110 Higgins
           Grant
           Zeuss

```

It is not clear from this result whether employees Grant and Zeuss have department_id NULL, or whether their department_id is not in the departments table. To determine this requires a full outer join:

```

SELECT d.department_id as d_dept_id, e.department_id as e_dept_id,
       e.last_name
  FROM departments d FULL OUTER JOIN employees e
    ON d.department_id = e.department_id
 ORDER BY d.department_id, e.last_name;

```

```

D_DEPT_ID  E_DEPT_ID LAST_NAME
-----
. . .
      110      110 Gietz
      110      110 Higgins
. . .
      260
      270
           999 Zeuss
           Grant

```

Because the column names in this example are the same in both tables in the join, you can also use the common column feature by specifying the USING clause of the join syntax. The output is the same as for the preceding example except that the USING clause coalesces the two matching columns department_id into a single column output:

```
SELECT department_id AS d_e_dept_id, e.last_name
   FROM departments d FULL OUTER JOIN employees e
     USING (department_id)
  ORDER BY department_id, e.last_name;
```

```
D_E_DEPT_ID LAST_NAME
-----
. . .
    110 Higgins
    110 Gietz
. . .
    260
    270
    999 Zeuss
        Grant
```

Using Partitioned Outer Joins: Examples

The following example shows how a partitioned outer join fills in gaps in rows to facilitate analytic calculation specification and reliable report formatting. The example first creates and populates a simple table to be used in the join:

```
CREATE TABLE inventory (time_id    DATE,
                        product     VARCHAR2(10),
                        quantity    NUMBER);

INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('06/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'can', 10);
INSERT INTO inventory VALUES (TO_DATE('04/04/01', 'DD/MM/YY'), 'can', 10);
```

```
SELECT times.time_id, product, quantity FROM inventory
   PARTITION BY (product)
  RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
 WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
    AND TO_DATE('06/04/01', 'DD/MM/YY')
  ORDER BY 2,1;
```

```
TIME_ID  PRODUCT      QUANTITY
-----
01-APR-01 bottle             10
02-APR-01 bottle
03-APR-01 bottle
04-APR-01 bottle
05-APR-01 bottle
06-APR-01 bottle             10
01-APR-01 can             10
02-APR-01 can
03-APR-01 can
04-APR-01 can             10
05-APR-01 can
06-APR-01 can
```

12 rows selected.

The data is now more dense along the time dimension for each partition of the product dimension. However, each of the newly added rows within each partition is null in the quantity

column. It is more useful to see the nulls replaced by the preceding non-NULL value in time order. You can achieve this by applying the analytic function `LAST_VALUE` on top of the query result:

```
SELECT time_id, product, LAST_VALUE(quantity IGNORE NULLS)
  OVER (PARTITION BY product ORDER BY time_id) quantity
  FROM ( SELECT times.time_id, product, quantity
        FROM inventory PARTITION BY (product)
        RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
        WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
          AND TO_DATE('06/04/01', 'DD/MM/YY'))
  ORDER BY 2,1;
```

TIME_ID	PRODUCT	QUANTITY
01-APR-01	bottle	10
02-APR-01	bottle	10
03-APR-01	bottle	10
04-APR-01	bottle	10
05-APR-01	bottle	10
06-APR-01	bottle	10
01-APR-01	can	10
02-APR-01	can	10
03-APR-01	can	10
04-APR-01	can	10
05-APR-01	can	10
06-APR-01	can	10

12 rows selected.

Oracle AI Database Data Warehousing Guide for an expanded discussion on filling gaps in time series calculations and examples of usage

Using Antijoins: Example

The following example selects a list of departments having no employee making 10000 or more as salary:

```
SELECT department_name FROM hr.departments d
WHERE NOT EXISTS (SELECT asdf FROM hr.employees e
                  WHERE e.department_id = d.department_id
                  AND e.salary >= 10000)
ORDER BY department_name;
```

Using Semijoins: Example

In the following example, only one row needs to be returned from the departments table, even though many rows in the employees table might match the subquery. If no index has been defined on the salary column in employees, then a semijoin can be used to improve query performance.

```
SELECT * FROM departments
WHERE EXISTS
  (SELECT * FROM employees
   WHERE departments.department_id = employees.department_id
   AND employees.salary >= 10000)
```

```

AND employees.salary > 2500)
ORDER BY department_name;

```

Using CROSS APPLY and OUTER APPLY Joins: Examples

The following statement uses the CROSS APPLY clause of the *cross_outer_apply_clause*. The join returns only rows from the table on the left side of the join (departments) that produce a result from the inline view on the right side of the join. That is, the join returns only the departments that have at least one employee. The WHERE clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. However, the Operations department is not included in the result set because it has no employees.

```

SELECT d.department_name, v.employee_id, v.last_name
FROM departments d CROSS APPLY (SELECT * FROM employees e
                                WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;

```

DEPARTMENT_NAME	EMPLOYEE_ID	LAST_NAME
Marketing	201	Hartstein
Marketing	202	Fay
Public Relations	204	Baer

The following statement uses the OUTER APPLY clause of the *cross_outer_apply_clause*. The join returns all rows from the table on the left side of the join (departments) regardless of whether they produce a result from the inline view on the right side of the join. That is, the join returns all departments regardless of whether the departments have any employees. The WHERE clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. The Operations department is included in the result set even though it has no employees.

```

SELECT d.department_name, v.employee_id, v.last_name
FROM departments d OUTER APPLY (SELECT * FROM employees e
                                WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;

```

DEPARTMENT_NAME	EMPLOYEE_ID	LAST_NAME
Marketing	201	Hartstein
Marketing	202	Fay
Operations		
Public Relations	204	Baer

Using Lateral Inline Views: Example

The following example shows a scalar subquery that finds the highest-paid employee in each department, with employee_id as a tie-breaker:

```

SELECT department_name,
       (SELECT last_name FROM
        (SELECT last_name FROM hr.employees e
         WHERE e.department_id = d.department_id
         ORDER BY e.salary DESC, e.employee_id ASC)
        WHERE ROWNUM = 1) highest_paid
FROM hr.departments d;

```

If you would like not only to see the highest-paid employee's last name, but also their first_name, salary, and email, as separate columns, the above approach would require 4

separate scalar subqueries. A LATERAL join in this case offers a way to extend a scalar-like subqueries to return any number of columns and other expressions that can then be referenced any number of times anywhere these could be referenced from an ordinary join, the SELECT list, the WHERE clause, ORDER BY, GROUP BY, and others, for example:

```
SELECT d.department_name, e2.last_name, e2.first_name, e2.salary, e2.email
FROM hr.departments d,
     LATERAL (SELECT * FROM
              (SELECT * FROM hr.employees e
               WHERE e.department_id = d.department_id
               ORDER BY e.salary DESC, e.employee_id ASC)
              WHERE ROWNUM = 1) e2;
```

Table Collections: Examples

You can perform DML operations on nested tables only if they are defined as columns of a table. Therefore, when the *query_table_expr_clause* of an INSERT, DELETE, or UPDATE statement is a *table_collection_expression*, the collection expression must be a subquery that uses the TABLE collection expression to select the nested table column of the table. The examples that follow are based on the following scenario:

Suppose the database contains a table `hr_info` with columns `department_id`, `location_id`, and `manager_id`, and a column of nested table type `people` which has `last_name`, `department_id`, and `salary` columns for all the employees of each respective manager:

```
CREATE TYPE people_typ AS OBJECT (
    last_name      VARCHAR2(25),
    department_id  NUMBER(4),
    salary         NUMBER(8,2));
/
CREATE TYPE people_tab_typ AS TABLE OF people_typ;
/
CREATE TABLE hr_info (
    department_id  NUMBER(4),
    location_id    NUMBER(4),
    manager_id     NUMBER(6),
    people         people_tab_typ)
    NESTED TABLE people STORE AS people_stor_tab;
```

```
INSERT INTO hr_info VALUES (280, 1800, 999, people_tab_typ());
```

The following example inserts into the `people` nested table column of the `hr_info` table for department 280:

```
INSERT INTO TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280)
VALUES ('Smith', 280, 1750);
```

The next example updates the department 280 `people` nested table:

```
UPDATE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
SET p.salary = p.salary + 100;
```

The next example deletes from the department 280 `people` nested table:

```
DELETE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
WHERE p.salary > 1700;
```

Collection Unnesting: Examples

To select data from a nested table column, use the `TABLE` collection expression to treat the nested table as columns of a table. This process is called **collection unnesting**.

You could get all the rows from `hr_info`, which was created in the preceding example, and all the rows from the `people` nested table column of `hr_info` using the following statement:

```
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(t1.people) t2
WHERE t2.department_id = t1.department_id;
```

Now suppose that `people` is not a nested table column of `hr_info`, but is instead a separate table with columns `last_name`, `department_id`, `address`, `hiredate`, and `salary`. You can extract the same rows as in the preceding example with this statement:

```
SELECT t1.department_id, t2.*
FROM hr_info t1, TABLE(CAST(MULTISET(
    SELECT t3.last_name, t3.department_id, t3.salary
    FROM people t3
    WHERE t3.department_id = t1.department_id)
AS people_tab_typ)) t2;
```

Finally, suppose that `people` is neither a nested table column of table `hr_info` nor a table itself. Instead, you have created a function `people_func` that extracts from various sources the name, department, and salary of all employees. You can get the same information as in the preceding examples with the following query:

```
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(CAST
    (people_func( ... ) AS people_tab_typ)) t2;
```

Oracle AI Database Object-Relational Developer's Guide for more examples of collection unnesting.

Using the LEVEL Pseudocolumn: Examples

The following statement returns all employees in hierarchical order. The root row is defined to be the employee whose job is `AD_VP`. The child rows of a parent row are defined to be those who have the employee number of the parent row as their manager number.

```
SELECT LPAD(' ', 2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
FROM employees
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

ORG_CHART	EMPLOYEE_ID	MANAGER_ID	JOB_ID
-----			-----
Kochhar	101	100	AD_VP
Greenberg	108	101	FI_MGR
Faviet	109	108	FI_ACCOUNT
Chen	110	108	FI_ACCOUNT
Sciarra	111	108	FI_ACCOUNT
Urman	112	108	FI_ACCOUNT
Popp	113	108	FI_ACCOUNT
Whalen	200	101	AD_ASST
Mavris	203	101	HR_REP
Baer	204	101	PR_REP
Higgins	205	101	AC_MGR
Gietz	206	205	AC_ACCOUNT

De Haan	102	100 AD_VP
Hunold	103	102 IT_PROG
Ernst	104	103 IT_PROG
Austin	105	103 IT_PROG
Pataballa	106	103 IT_PROG
Lorentz	107	103 IT_PROG

The following statement is similar to the previous one, except that it does not select employees with the job FI_MGR.

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
FROM employees
WHERE job_id != 'FI_MGR'
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

ORG_CHART	EMPLOYEE_ID	MANAGER_ID	JOB_ID
-----	-----	-----	-----
Kochhar	101	100 AD_VP	
Faviet	109	108 FI_ACCOUNT	
Chen	110	108 FI_ACCOUNT	
Sciarra	111	108 FI_ACCOUNT	
Urman	112	108 FI_ACCOUNT	
Popp	113	108 FI_ACCOUNT	
Whalen	200	101 AD_ASST	
Mavris	203	101 HR_REP	
Baer	204	101 PR_REP

Ernst	104	103 IT_PROG	
Austin	105	103 IT_PROG	
Pataballa	106	103 IT_PROG	
Lorentz	107	103 IT_PROG	

The database does not return the manager Greenberg, although it does return employees who are managed by Greenberg.

The following statement is similar to the first one, except that it uses the LEVEL pseudocolumn to select only the first two levels of the management hierarchy:

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
FROM employees
START WITH job_id = 'AD_PRES'
CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 2;
```

ORG_CHART	EMPLOYEE_ID	MANAGER_ID	JOB_ID
-----	-----	-----	-----
King	100	AD_PRES	
Kochhar	101	100 AD_VP	
De Haan	102	100 AD_VP	
Raphaely	114	100 PU_MAN	
Weiss	120	100 ST_MAN	
Fripp	121	100 ST_MAN	
Kaufling	122	100 ST_MAN	
Vollman	123	100 ST_MAN	
Mourgos	124	100 ST_MAN	
Russell	145	100 SA_MAN	

Partners	146	100 SA_MAN
Errazuriz	147	100 SA_MAN
Cambrault	148	100 SA_MAN
Zlotkey	149	100 SA_MAN
Hartstein	201	100 MK_MAN

Using Distributed Queries: Example

This example shows a query that joins the departments table on the local database with the employees table on the remote database:

```
SELECT last_name, department_name
FROM employees@remote, departments
WHERE employees.department_id = departments.department_id;
```

Using Correlated Subqueries: Examples

The following examples show the general syntax of a correlated subquery:

```
SELECT select_list
FROM table1 t_alias1
WHERE expr operator
      (SELECT column_list
FROM table2 t_alias2
WHERE t_alias1.column
      operator t_alias2.column);

UPDATE table1 t_alias1
SET column =
      (SELECT expr
FROM table2 t_alias2
WHERE t_alias1.column = t_alias2.column);

DELETE FROM table1 t_alias1
WHERE column operator
      (SELECT expr
FROM table2 t_alias2
WHERE t_alias1.column = t_alias2.column);
```

The following statement returns data about employees whose salaries exceed their department average. The following statement assigns an alias to employees, the table containing the salary information, and then uses the alias in a correlated subquery:

```
SELECT department_id, last_name, salary
FROM employees x
WHERE salary > (SELECT AVG(salary)
FROM employees
WHERE x.department_id = department_id)
ORDER BY department_id;
```

For each row of the employees table, the parent query uses the correlated subquery to compute the average salary for members of the same department. The correlated subquery performs the following steps for each row of the employees table:

1. The department_id of the row is determined.
2. The department_id is then used to evaluate the parent query.
3. If the salary in that row is greater than the average salary of the departments of that row, then the row is returned.

The subquery is evaluated once for each row of the employees table.

Selecting from the DUAL Table: Example

The following statement returns the current date:

```
SELECT CURRENT_DATE FROM DUAL;
```

You could select `CURRENT_DATE` from the `employees` table, but the database would return 14 rows of the same `CURRENT_DATE`, one for every row of the `employees` table. Selecting from `DUAL` is more convenient.

From Release 23 you can omit the optional `FROM` clause as in the following example:

```
SELECT CURRENT_DATE;
```

Selecting Sequence Values: Examples

The following statement increments the `employees_seq` sequence and returns the new value:

```
SELECT employees_seq.nextval  
FROM DUAL;
```

The following statement selects the current value of `employees_seq`:

```
SELECT employees_seq.currval  
FROM DUAL;
```

Row Pattern Matching: Example

This example uses row pattern matching to query stock price data. The following statements create table `Ticker` and inserts stock price data into the table:

```
CREATE TABLE Ticker (SYMBOL VARCHAR2(10), tstamp DATE, price NUMBER);
```

```
INSERT INTO Ticker VALUES('ACME', '01-Apr-11', 12);  
INSERT INTO Ticker VALUES('ACME', '02-Apr-11', 17);  
INSERT INTO Ticker VALUES('ACME', '03-Apr-11', 19);  
INSERT INTO Ticker VALUES('ACME', '04-Apr-11', 21);  
INSERT INTO Ticker VALUES('ACME', '05-Apr-11', 25);  
INSERT INTO Ticker VALUES('ACME', '06-Apr-11', 12);  
INSERT INTO Ticker VALUES('ACME', '07-Apr-11', 15);  
INSERT INTO Ticker VALUES('ACME', '08-Apr-11', 20);  
INSERT INTO Ticker VALUES('ACME', '09-Apr-11', 24);  
INSERT INTO Ticker VALUES('ACME', '10-Apr-11', 25);  
INSERT INTO Ticker VALUES('ACME', '11-Apr-11', 19);  
INSERT INTO Ticker VALUES('ACME', '12-Apr-11', 15);  
INSERT INTO Ticker VALUES('ACME', '13-Apr-11', 25);  
INSERT INTO Ticker VALUES('ACME', '14-Apr-11', 25);  
INSERT INTO Ticker VALUES('ACME', '15-Apr-11', 14);  
INSERT INTO Ticker VALUES('ACME', '16-Apr-11', 12);  
INSERT INTO Ticker VALUES('ACME', '17-Apr-11', 14);  
INSERT INTO Ticker VALUES('ACME', '18-Apr-11', 24);  
INSERT INTO Ticker VALUES('ACME', '19-Apr-11', 23);  
INSERT INTO Ticker VALUES('ACME', '20-Apr-11', 22);
```

The following query uses row pattern matching to find all cases where stock prices dipped to a bottom price and then rose. This is generally called a V-shape. The resulting output contains only three rows because the query specifies `ONE ROW PER MATCH`, and three matches were found.

```
SELECT *  
FROM Ticker MATCH_RECOGNIZE (  
    PARTITION BY symbol  
    ORDER BY tstamp
```

```

    MEASURES STRT.tstamp AS start_tstamp,
              LAST(DOWN.tstamp) AS bottom_tstamp,
              LAST(UP.tstamp) AS end_tstamp
    ONE ROW PER MATCH
    AFTER MATCH SKIP TO LAST UP
    PATTERN (STRT DOWN+ UP+)
    DEFINE
        DOWN AS DOWN.price < PREV(DOWN.price),
        UP AS UP.price > PREV(UP.price)
    ) MR
ORDER BY MR.symbol, MR.start_tstamp;

SYMBOL      START_TST BOTTOM_TS END_TSTAM
-----
ACME         05-APR-11 06-APR-11 10-APR-11
ACME         10-APR-11 12-APR-11 13-APR-11
ACME         14-APR-11 16-APR-11 18-APR-11

```

Partitioned Row Limiting in Non-Vector Context: Example

The following example finds the top two departments that people with highest salary work in, and the top three people with the highest salary within each selected department:

```

SELECT deptno, ename FROM emp
ORDER BY sal DESC
FETCH FIRST 2 PARTITIONS BY deptno, 3 ROWS ONLY;

```

Partitioned Row Limiting in a Multi-Vector Search: Example

The following statement creates a table `chunk_table` with three columns: `doc_id` and `chunk_id` (of type NUMBER), and `data_vec` (of type VECTOR).

`doc_id` refers to the document id, `chunk_id` refers to the chunk id, and `data_vec` refers to the vector embedding.

```

CREATE TABLE chunk_table (
    doc_id NUMBER,
    chunk_id NUMBER,
    data_vec VECTOR
);

```

The following query performs a multi-vector search :

```

SELECT doc_id,
       FROM chunk_table
       ORDER BY VECTOR_DISTANCE(data_vec, :query_vec)
       FETCH [APPROX] FIRST 10 PARTITIONS BY docId, 1 ROW ONLY;

```

QUALIFY Clause: Examples

Analytic function in QUALIFY Clause

```

SELECT ENAME, SAL, DNAME, LOC
FROM EMP, DEPT
WHERE EMP.DEPTNO = DEPT.DEPTNO
QUALIFY AVG(SAL) OVER (PARTITION BY LOC) > 2000
ORDER BY ENAME;

```

The output is:

ENAME	SAL	DNAME	LOC
ADAMS	1100	RESEARCH	DALLAS
CLARK	2450	ACCOUNTING	NEW YORK

Query with GROUPING SETS and QUALIFY clause

```
SELECT DNAME, MGR, AVG(SAL), AVG(AVG(SAL)) OVER W AS AVG_SAL_WF
FROM EMP, DEPT WHERE EMP.DEPTNO = DEPT.DEPTNO
GROUP BY GROUPING SETS ((DNAME), (MGR))
WINDOW W AS (PARTITION BY DNAME)
QUALIFY AVG_SAL_WF > 2000
ORDER BY DNAME;
```

The output is:

DNAME	MGR	AVG(SAL)	AVG_SAL_WF
ACCOUNTING		2916.66667	2916.66667
RESEARCH		2175	2175
SALES		1566.66667	1566.66667

```

7566      3000 2181.19048
7788      1100 2181.19048
7782      1300 2181.19048
7839 2758.33333 2181.19048
7698      1310 2181.19048
7902       800 2181.19048
          5000 2181.19048

```

10 rows selected.

QUALIFY Clause With Compound Logical Predicates: Examples

```

SELECT JOB, AVG(SAL)
FROM EMP
GROUP BY JOB
HAVING JOB IS NOT NULL
QUALIFY AVG(SAL) < 2000;

```

```

SELECT SAL
FROM EMP
WHERE JOB IS NOT NULL
QUALIFY SAL < 2000;

```

```

SELECT ENAME, SAL,
       AVG(SAL) OVER WJ AS A1,
       AVG(SAL) OVER WD AS A2
FROM SCOTT.EMP
WINDOW WJ AS (PARTITION BY JOB), WD AS (PARTITION BY DEPTNO)
QUALIFY A1 > 2073.21429 AND A2 > 2073.21429
ORDER BY ENAME;

```

JOIN TO ONE: Example

```

SELECT oi.unit_price*oi.quantity line_val, o.order_id, o.order_status, p.product_name,
       c.cust_email
FROM oe.Order_Items oi JOIN TO ONE
      (oe.Orders o, oe.Product_Information p, oe.Customers c)
ORDER BY o.order_id, oi.line_item_id;

```

In the OE schema on FreeSQL, the necessary foreign keys and primary keys are defined so that JOIN TO ONE can fill in the join clauses for you. The query will run with no runtime overhead to confirm already-key-guaranteed join-uniqueness. The query result returns precisely one row per row of the RWT oe.Order_Items, that always precedes JOIN TO ONE. If you choose to make joins explicit, both in terms of join type and ON clauses, the logically equivalent query would be:

```

SELECT oi.unit_price*oi.quantity line_val, o.order_id, o.order_status, p.product_name,
       c.cust_email
FROM oe.Order_Items oi JOIN TO ONE
      (LEFT OUTER JOIN oe.Orders o ON oi.order_id=o.order_id
      LEFT OUTER JOIN oe.Product_Information p ON oi.product_id=p.product_id
      LEFT OUTER JOIN oe.Customers c ON o.customer_id=c.customer_id)
ORDER BY o.order_id, oi.line_item_id;

```

Nested WITH Clause: Example

The following query finds staff who earn more than the average of the first two people hired in their department. It then calculates the total salaries per department for these staff. Finally it returns the lowest and highest of these department totals.

It does this by nesting WITH clauses inside each other. The subquery `first_two_dept_hires` finds the first two hires in each department. The nested WITH `earn_gt_dept_first_2_hires` returns the staff who earn more than this average for their department. The outer WITH `dept_totals` calculates total salary per department for the rows returned by `earn_gt_dept_first_2_hires`.

```
WITH dept_totals AS (  
  WITH earn_gt_dept_first_2_hires AS (  
    SELECT * FROM hr.employees all_emp  
    WHERE salary > (  
      WITH first_two_dept_hires AS (  
        SELECT * FROM hr.employees first_2  
        WHERE first_2.department_id = all_emp.department_id -- correlated  
        ORDER BY hire_date FETCH FIRST 2 ROWS ONLY  
      )  
      SELECT AVG ( salary )  
      FROM first_two_dept_hires  
    )  
    SELECT department_id, SUM ( salary ) total_sal  
    FROM earn_gt_dept_first_2_hires  
    GROUP BY ALL  
  )  
  SELECT MIN ( total_sal ), MAX ( total_sal )  
  FROM dept_totals;
```

SET CONSTRAINT[S]

Purpose

Use the SET CONSTRAINTS statement to specify, for a particular transaction, whether a deferrable constraint is checked following each DML statement (IMMEDIATE) or when the transaction is committed (DEFERRED). You can use this statement to set the mode for a list of constraint names or for ALL constraints.

You can use SET CONSTRAINTS for assertions. When you use it for assertions, you must ensure that constraint names and assertion names are unique so they can live in the same namespace.

The SET CONSTRAINTS mode lasts for the duration of the transaction or until another SET CONSTRAINTS statement resets the mode.

Note

You can also use an ALTER SESSION statement with the SET CONSTRAINTS clause to set *all* deferrable constraints. This is equivalent to making issuing a SET CONSTRAINTS statement at the start of each transaction in the current session.

You cannot specify this statement inside of a trigger definition.

SET CONSTRAINTS can be a distributed statement. Existing database links that have transactions in process are notified when a SET CONSTRAINTS ALL statement is issued, and new links are notified that it was issued as soon as they start a transaction.

Prerequisites

To specify when a deferrable constraint is checked, you must have the READ or SELECT privilege on the table to which the constraint is applied unless the table is in your schema.

Syntax

set_constraints ::=

Semantics

constraint

Specify the name of one or more integrity constraints.

ALL

Specify ALL to set all deferrable constraints for this transaction.

IMMEDIATE

Specify IMMEDIATE to cause the specified constraints to be checked immediately on execution of each constrained DML statement. Oracle Database first checks any constraints that were deferred earlier in the transaction and then continues immediately checking constraints of any further statements in that transaction, as long as all the checked constraints are consistent and no other SET CONSTRAINTS statement is issued. If any constraint fails the check, then an error is signaled. At that point, a COMMIT statement causes the whole transaction to undo.

Making constraints immediate at the end of a transaction is a way of checking whether COMMIT can succeed. You can avoid unexpected rollbacks by setting constraints to IMMEDIATE as the last statement in a transaction. If any constraint fails the check, you can then correct the error before committing the transaction.

DEFERRED

Specify DEFERRED to indicate that the conditions specified by the deferrable constraint are checked when the transaction is committed.

Note

You can verify the success of deferrable constraints prior to committing them by issuing a SET CONSTRAINTS ALL IMMEDIATE statement.

Examples

Setting Constraints: Examples

The following statement sets all deferrable constraints in this transaction to be checked immediately following each DML statement:

```
SET CONSTRAINTS ALL IMMEDIATE;
```

The following statement checks three deferred constraints when the transaction is committed. This example fails if the constraints were specified to be NOT DEFERRABLE.

```
SET CONSTRAINTS emp_job_nn, emp_salary_min,  
hr.jhist_dept_fk@remote DEFERRED;
```

SET ROLE

Purpose

When a user logs on to Oracle Database, the database enables all privileges granted explicitly to the user and all privileges in the user's default roles. During the session, the user or an application can use the SET ROLE statement any number of times to enable or disable the roles currently enabled for the session.

You cannot enable more than 148 user-defined roles at one time.

Note

- For most roles, you cannot enable or disable a role unless it was granted to you either directly or through other roles. However, a secure application role can be granted and enabled by its associated PL/SQL package. See the CREATE ROLE semantics for [USING package](#) and *Oracle Database Security Guide* for information about secure application roles.
- SET ROLE succeeds only if there are no definer's rights units on the call stack. If at least one DR unit is on the call stack, then issuing the SET ROLE command causes ORA-06565. See *Oracle Database PL/SQL Language Reference* for more information about definer's rights units.
- To run the SET ROLE command from PL/SQL, you must use dynamic SQL, preferably the EXECUTE IMMEDIATE statement. See *Oracle Database PL/SQL Language Reference* for more information about this statement.

You can see which roles are currently enabled by examining the SESSION_ROLES data dictionary view.

See Also

- [CREATE ROLE](#) for information on creating roles
- [ALTER USER](#) for information on changing a user's default roles
- *Oracle Database Reference* for information on the SESSION_ROLES session parameter

Prerequisites

You must already have been granted the roles that you name in the SET ROLE statement.

Syntax

set_role::=

Semantics

role

Specify one or more roles to be enabled for the current session. All roles not specified are disabled for the current session or until another SET ROLE statement is issued in the current session.

In the IDENTIFIED BY *password* clause, specify the password for a role. If the role has a password, then you must specify the password to enable the role.

Restriction on Setting Roles

You cannot specify a role identified globally. Global roles are enabled by default at login, and cannot be reenabled later.

IDENTIFIED BY

You can set the password to a maximum length of 1024 bytes.

ALL Clause

Specify ALL to enable all roles granted to you for the current session except those optionally listed in the EXCEPT clause.

Roles listed in the EXCEPT clause must be roles granted directly to you. They cannot be roles granted to you through other roles.

If you list a role in the EXCEPT clause that has been granted to you both directly and through another role, then the role remains enabled by virtue of the role to which it has been granted.

Restrictions on the ALL Clause

The following restrictions apply to the ALL clause:

- You cannot use this clause to enable roles with passwords that have been granted directly to you.

- You cannot use this clause to enable a secure application role, which is a role that can be enabled only by applications using an authorized package. Refer to *Oracle Database Security Guide* for information on creating a secure application role.

NONE

Specify NONE to disable all roles for the current session, including the DEFAULT role.

Examples

Setting Roles: Examples

To enable the role `dw_manager` identified by a password for your current session, issue the following statement:

```
SET ROLE dw_manager IDENTIFIED BY password;
```

To enable all roles granted to you for the current session, issue the following statement:

```
SET ROLE ALL;
```

To enable all roles granted to you except `dw_manager`, issue the following statement:

```
SET ROLE ALL EXCEPT dw_manager;
```

To disable all roles granted to you for the current session, issue the following statement:

```
SET ROLE NONE;
```

SET TRANSACTION

Purpose

Use the SET TRANSACTION statement to establish the current transaction as read-only or read/write, establish its isolation level, assign it to a specified rollback segment, or assign a name to the transaction.

A transaction implicitly begins with any operation that obtains a TX lock:

- When a statement that modifies data is issued
- When a SELECT ... FOR UPDATE statement is issued
- When a transaction is explicitly started with a SET TRANSACTION statement or the DBMS_TRANSACTION package

Issuing either a COMMIT or ROLLBACK statement explicitly ends the current transaction.

The operations performed by a SET TRANSACTION statement affect only your current transaction, not other users or other transactions. Your transaction ends whenever you issue a COMMIT or ROLLBACK statement. Oracle Database implicitly commits the current transaction before and after executing a data definition language (DDL) statement.

① See Also

[COMMIT](#) and [ROLLBACK](#)

Prerequisites

If you use a SET TRANSACTION statement, then it must be the first statement in your transaction. However, a transaction need not have a SET TRANSACTION statement.

Syntax

set_transaction ::=

Semantics

READ ONLY

The READ ONLY clause establishes the current transaction as a read-only transaction. This clause established **transaction-level read consistency**.

All subsequent queries in that transaction see only changes that were committed before the transaction began. Read-only transactions are useful for reports that run multiple queries against one or more tables while other users update these same tables.

This clause is not supported for the user SYS. Queries by SYS will return changes made during the transaction even if SYS has set the transaction to be READ ONLY.

Restriction on Read-only Transactions

Only the following statements are permitted in a read-only transaction:

- Subqueries—SELECT statements without the *for_update_clause*
- LOCK TABLE
- SET ROLE
- ALTER SESSION
- ALTER SYSTEM

READ WRITE

Specify READ WRITE to establish the current transaction as a read/write transaction. This clause establishes **statement-level read consistency**, which is the default.

Restriction on Read/Write Transactions

You cannot toggle between transaction-level and statement-level read consistency in the same transaction.

ISOLATION LEVEL Clause

- The `SERIALIZABLE` setting specifies serializable transaction isolation mode as defined in the SQL standard. If a serializable transaction contains data manipulation language (DML) that attempts to update any resource that may have been updated in a transaction uncommitted at the start of the serializable transaction, then the DML statement fails.
- The `READ COMMITTED` setting is the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement waits until the row locks are released.

USE ROLLBACK SEGMENT Clause

Note

This clause is relevant and valid only if you are using rollback segments for undo. Oracle strongly recommends that you use automatic undo management to handle undo space. If you follow this recommendation and run your database in automatic undo mode, then Oracle Database ignores this clause.

Specify `USE ROLLBACK SEGMENT` to assign the current transaction to the specified rollback segment. This clause also implicitly establishes the transaction as a read/write transaction.

Parallel DML requires more than one rollback segment. Therefore, if your transaction contains parallel DML operations, then the database ignores this clause.

NAME Clause

Use the `NAME` clause to assign a name to the current transaction. This clause is especially useful in distributed database environments when you must identify and resolve in-doubt transactions. The *string* value is limited to 255 bytes.

If you specify a name for a distributed transaction, then when the transaction commits, the name becomes the commit comment, overriding any comment specified explicitly in the `COMMIT` statement.

See Also

Oracle Database Concepts for more information about transaction naming

Examples

Setting Transactions: Examples

The following statements could be run at midnight of the last day of every month to count the products and quantities on hand in the West Coast warehouses in the sample Order Entry (oe) schema. This report would not be affected by any other user who might be adding or removing inventory to a different warehouse between the running of the first query and the running of the second query.

```
COMMIT;
```

```
SET TRANSACTION READ ONLY NAME 'West Coast';
```

```
SELECT product_id, quantity_on_hand, 'San Francisco' location
FROM inventories
WHERE warehouse_id = 2
ORDER BY product_id;
```

```
SELECT product_id, quantity_on_hand, 'Seattle' location
FROM inventories
WHERE warehouse_id = 4
ORDER BY product_id;
```

```
COMMIT;
```

The first COMMIT statement ensures that SET TRANSACTION is the first statement in the transaction. The last COMMIT statement does not actually make permanent any changes to the database. It simply ends the read-only transaction.

SET USE DATA GRANTS ONLY

Purpose

Use SET USE DATA GRANTS ONLY to enable mandatory access control for a table or view. Mandatory access control restricts DML access to the table or view by requiring data grants for Deep Sec users. This means that without data grants, Deep Sec users will not be allowed to access the table or view even if they are granted database privileges.

Perequisites

You must have the SET USE DATA GRANTS ONLY privilege at the system level or on the object's schema in order to execute this command.

Syntax

Semantics

- schema.object*: refers to the table or view you want to set mandatory access control on. This means that only the data grants will be checked and honored for object access.
If USE DATA GRANTS ONLY is enabled for an object and no data grants are present for the object, then the Deep Sec user will not be able to access the object.
Note that this setting is applicable and enforced only for Deep Sec users.
- ENABLED | DISABLED: refers to whether the command should be disabled or enabled for the object. The default value is ENABLED.

Examples

Example 1

In the example below an employee is granted access to both `hr.employees_view` and the base table `hr.employees`:

```
CREATE VIEW hr.employees_view
  AS SELECT * FROM hr.employees;
```

Grant SELECT DATA privilege on the view `hr.employees_view`:

```
CREATE OR REPLACE DATA GRANT app_admin.EmployeesViewGrant
  AS
  SELECT
    ON hr.employees_view
  TO app_employee_role;
```

Grant DATA privilege on the base table `hr.employees`:

```
CREATE OR REPLACE DATA GRANT
  app_admin.EmployeesOwnRecord AS
  SELECT
    ON hr.employees
  WHERE name = ORA_END_USER_CONTEXT.username
  TO app_employee_role;
```

When employees access `hr.employees`, they can only view their own record:

```
SELECT name FROM hr.employees;
```

```
NAME
-----
Marvin
1 row selected.
```

When they access the view `hr.employees_view`, they can view all the rows as the base table is accessed as the view owner `hr`:

```
SELECT name FROM hr.employees_view;
```

```
NAME
-----
Marvin
John
Daniel
3 rows selected.
```

When `USE DATA GRANTS ONLY` is enabled, employees only see their own row regardless of how they access the table (directly or through a view), or what database privileges they are granted. Once enabled, data privileges are always checked and enforced regardless of the mode of access. The following example illustrates this:

```
SET USE DATA GRANTS ONLY ON hr.employees ENABLED;
```

```
SELECT name FROM hr.employees;
```

```
NAME
-----
Marvin
1 row selected.
```

```
SELECT name FROM hr.employees_view;
```

```
NAME
-----
Marvin
1 row selected.
```

Example 2

The following example illustrates this scenario:

The view `hr.employees_personal_info` is defined on view `hr.employees_view` which is defined on `hr.employees` base table.

If `USE DATA GRANTS ONLY` is enabled for `hr.employees_view`, then the Deep Sec user will need a data grant or object privilege on `hr.employees_view_personal_info` and data grant on `hr.employees_view`. `hr.employees` base table will be accessed as the view owner.

Create a view `hr.employees_view` in the `hr` schema:

```
CREATE VIEW hr.employees_view
AS SELECT * FROM hr.employees;
```

Create a view `hr.employees_personal_info` in the `hr` schema on `hr.employees_view`:

```
CREATE VIEW hr.employees_personal_info
AS SELECT name, phone_number, email
FROM hr.employees_view;
```

Grant data privilege on `hr.employees_personal_info`:

```
CREATE OR REPLACE DATA GRANT
app_admin.EmployeesPersonalInfoGrant AS
SELECT
```

```
ON hr.employees_personal_info
WHERE name = ORA_END_USER_CONTEXT.username
TO app_employee_role;
```

SET USE DATA GRANTS ONLY on hr.employees_view:

```
SET USE DATA GRANTS ONLY
ON hr.employees_view ENABLED;
```

When employee queries hr.employees_personal_info, they do not see any data as they need the data grant on hr.employees_view as SET USE DATA GRANTS ONLY is enabled on hr.employees_view:

```
SELECT name FROM hr.employees_personal_info;

NAME
-----
0 rows selected.
```

Grant data privilege on hr.employees_view:

```
CREATE OR REPLACE DATA GRANT
app_admin.EmployeesViewGrant AS
SELECT (name, phone_number, email)
ON hr.employees_view
WHERE name = ORA_END_USER_CONTEXT.username
TO app_employee_role;
```

Employee queries the view hr.employees_personal_info and can see their record:

```
NAME
-----
Marvin

1 row selected.
```

TRUNCATE CLUSTER

Purpose

① Note

You cannot roll back a TRUNCATE CLUSTER statement.

Use the `TRUNCATE CLUSTER` statement to remove all rows from a cluster. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the `MINEXTENTS` storage parameter
- Sets the `NEXT` storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the `TRUNCATE` statement can be more efficient than dropping and re-creating a cluster. Dropping and re-creating a cluster invalidates dependent objects of the cluster, requires you to regrant object privileges on the cluster, and requires you to re-create the indexes and cluster on the table and respecify its storage parameters. Truncating has none of these effects.

Removing rows with the `TRUNCATE CLUSTER` statement can be faster than removing all rows with the `DELETE` statement, especially if the cluster has numerous indexes and other dependencies.

See Also

- [DELETE](#) and [DROP CLUSTER](#) for information on other ways of dropping data from a cluster
- [TRUNCATE TABLE](#) for information on truncating a table

Prerequisites

You must have the `DROP ANY CLUSTER` and `DROP ANY TABLE` system or schema privileges to truncate a cluster. You must be able to drop a cluster to be able to truncate it or have the sufficient privileges to truncate a cluster. Additionally, you must have the privileges to drop all tables related to the cluster or have the `DROP ANY TABLE` system or schema privilege.

See Also

["Restrictions on Truncating Tables"](#)

Syntax

truncate_cluster::=

Semantics

CLUSTER Clause

Specify the schema and name of the cluster to be truncated. You can truncate only an indexed cluster, not a hash cluster. If you omit *schema*, then the database assumes the cluster is in your own schema.

When you truncate a cluster, the database also automatically deletes all data in the indexes of the cluster tables.

STORAGE Clauses

The STORAGE clauses let you determine what happens to the space freed by the truncated rows. The DROP STORAGE clause and REUSE STORAGE clause also apply to the space freed by the data deleted from associated indexes.

DROP STORAGE

Specify DROP STORAGE to deallocate all space from the deleted rows from the cluster except the space allocated by the MINEXTENTS parameter of the cluster. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the NEXT storage parameter to the size of the last extent removed from the segment in the truncation process. This is the default.

REUSE STORAGE

Specify REUSE STORAGE to retain the space from the deleted rows allocated to the cluster. Storage values are not reset to the values when the table or cluster was created. This space can subsequently be used only by new data in the cluster resulting from insert or update operations. This clause leaves storage parameters at their current settings.

If you have specified more than one free list for the object you are truncating, then the REUSE STORAGE clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

Examples

Truncating a Cluster: Example

The following statement removes all rows from all tables in the personnel cluster, but leaves the freed space allocated to the tables:

```
TRUNCATE CLUSTER personnel REUSE STORAGE;
```

The preceding statement also removes all data from all indexes on the tables in the personnel cluster.

TRUNCATE TABLE

Purpose

Note

You cannot roll back a TRUNCATE TABLE statement, nor can you use a FLASHBACK TABLE statement to retrieve the contents of a table that has been truncated.

Use the TRUNCATE TABLE statement to remove all rows from a table. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the MINEXTENTS storage parameter

When Flashback Database is enabled, TRUNCATE will not deallocate space immediately by default. This allows the Flashback block new optimization to be more effective. The DROP STORAGE clause is required to deallocate space immediately.

- Sets the NEXT storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the TRUNCATE TABLE statement can be more efficient than dropping and re-creating a table. Dropping and re-creating a table invalidates dependent objects of the table, and requires you to repeat the following actions:

- Grant object privileges on the table
- Create the indexes, integrity constraints, and triggers on the table
- Specify the storage parameters of the table

Truncating has none of these effects.

Removing rows with the TRUNCATE TABLE statement can be faster than removing all rows with the DELETE statement, especially if the table has numerous triggers, indexes, and other dependencies.

① See Also

- [DELETE](#) and [DROP TABLE](#) for information on other ways of removing data from a table
- [TRUNCATE CLUSTER](#) for information on truncating a cluster

Prerequisites

To truncate a table, the table must be in your schema or you must have the DROP ANY TABLE system privilege.

To specify the CASCADE clause, all affected child tables must be in your schema or you must have the DROP ANY TABLE system privilege.

You can truncate a private temporary table with the existing TRUNCATE TABLE command. Truncating a private temporary table will not commit and existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a truncated private temporary table will not go into the RECYCLEBIN.

① See Also

["Restrictions on Truncating Tables"](#)

Syntax

truncate_table::=

Semantics

TABLE Clause

Specify the schema and name of the table to be truncated. This table cannot be part of a cluster. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

- You can truncate index-organized tables and temporary tables. When you truncate a temporary table, only the rows created during the current session are removed.
- Oracle Database changes the `NEXT` storage parameter of *table* to be the size of the last extent deleted from the segment in the process of truncation.
- Oracle Database also automatically truncates and resets any existing `UNUSABLE` indicators for the following indexes on *table*: range and hash partitions of local indexes and subpartitions of local indexes.
- If *table* is not empty, then the database marks `UNUSABLE` all nonpartitioned indexes and all partitions of global partitioned indexes on the table. However, when the table is truncated, the index is also truncated, and a new high water mark is calculated for the index segment. This operation is equivalent to creating a new segment for the index. Therefore, at the end of the truncate operation, the indexes are once again `USABLE`.
- For a domain index, this statement invokes the appropriate truncate routine to truncate the domain index data.

See Also

Oracle Database Data Cartridge Developer's Guide for more information on domain indexes

- If a regular or index-organized table contains LOB columns, then all LOB data and LOB index segments are truncated.
- If *table* is partitioned, then all partitions or subpartitions, as well as the LOB data and LOB index segments for each partition or subpartition, are truncated.

Note

When you truncate a table, Oracle Database automatically removes all data in the table's indexes and any materialized view direct-path INSERT information held in association with the table. This information is independent of any materialized view log. If this direct-path INSERT information is removed, then an incremental refresh of the materialized view may lose data.

- All cursors are invalidated.

Restrictions on Truncating Tables

This statement is subject to the following restrictions:

- You cannot roll back a TRUNCATE TABLE statement.
- You cannot flash back to the state of the table before the truncate operation.
- You cannot individually truncate a table that is part of a cluster. You must either truncate the cluster, delete all rows from the table, or drop and re-create the table.
- You cannot truncate the parent table of an enabled foreign key constraint. You must disable the constraint before truncating the table. An exception is that you can truncate the table if the integrity constraint is self-referential.
- If a domain index is defined on *table*, then neither the index nor any index partitions can be marked IN_PROGRESS.
- You cannot truncate the parent table of a reference-partitioned table. You must first drop the reference-partitioned child table.
- You cannot truncate a duplicated table.

MATERIALIZED VIEW LOG Clause

The MATERIALIZED VIEW LOG clause lets you specify whether a materialized view log defined on the table is to be preserved or purged when the table is truncated. This clause permits materialized view master tables to be reorganized through export or import without affecting the ability of primary key materialized views defined on the master to be fast refreshed. To support continued fast refresh of primary key materialized views, the materialized view log must record primary key information.

Note

The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

PRESERVE

Specify PRESERVE if any materialized view log should be preserved when the master table is truncated. This is the default.

PURGE

Specify PURGE if any materialized view log should be purged when the master table is truncated.

① See Also

Oracle Database Administrator's Guide for more information about materialized view logs and the TRUNCATE statement

STORAGE Clauses

The STORAGE clauses let you determine what happens to the space freed by the truncated rows. The DROP STORAGE clause, DROP ALL STORAGE clause, and REUSE STORAGE clause also apply to the space freed by the data deleted from associated indexes.

DROP STORAGE

Specify DROP STORAGE to deallocate all space from the deleted rows from the table except the space allocated by the MINEXTENTS parameter of the table. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the NEXT storage parameter to the size of the last extent removed from the segment in the truncation process. This setting, which is the default, is useful for small and medium-sized objects. The extent management in locally managed tablespace is very fast in these cases, so there is no need to reserve space.

DROP ALL STORAGE

Specify DROP ALL STORAGE to deallocate all space from the deleted rows from the table, including the space allocated by the MINEXTENTS parameter. All segments for the table, as well as all segments for its dependent objects, will be deallocated.

Restrictions on DROP ALL STORAGE

This clause is subject to the same restrictions as described in "[Restrictions on Deferred Segment Creation](#)".

REUSE STORAGE

Specify REUSE STORAGE to retain the space from the deleted rows allocated to the table. Storage values are not reset to the values when the table was created. This space can subsequently be used only by new data in the table resulting from insert or update operations. This clause leaves storage parameters at their current settings.

This setting is useful as an alternative to deleting all rows of a very large table—when the number of rows is very large, the table entails many thousands of extents, and when data is to be reinserted in the future.

This clause is not valid for temporary tables. A session becomes unbound from the temporary table when the table is truncated, so the storage is automatically dropped.

If you have specified more than one free list for the object you are truncating, then the REUSE STORAGE clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

CASCADE

If you specify CASCADE, then Oracle Database truncates all child tables that reference *table* with an enabled ON DELETE CASCADE referential constraint. This is a recursive operation that will truncate all child tables, grandchild tables, and so on, using the specified options.

Examples

Truncating a Table: Example

The following statement removes all rows from a hypothetical copy of the sample table `hr.employees` and returns the freed space to the tablespace containing `employees`:

```
TRUNCATE TABLE employees_demo;
```

The preceding statement also removes all data from all indexes on `employees` and returns the freed space to the tablespaces containing them.

Preserving Materialized View Logs After Truncate: Example

The following statements are examples of `TRUNCATE` statements that preserve materialized view logs:

```
TRUNCATE TABLE sales_demo PRESERVE MATERIALIZED VIEW LOG;
```

```
TRUNCATE TABLE orders_demo;
```

UPDATE

Purpose

Use the `UPDATE` statement to change existing values in a table or in the base table of a view or the master table of a materialized view.

Prerequisites

For you to update values in a table, the table must be in your own schema or you must have the `UPDATE` object privilege on the table.

For you to update values in the base table of a view:

- You must have the `UPDATE` object privilege on the view, and
- Whoever owns the schema containing the view must have the `UPDATE` object privilege on the base table.

The `UPDATE ANY TABLE` system privilege also allows you to update values in any table or in the base table of any view.

To update values in an object on a remote database, you must also have the `READ` or `SELECT` object privilege on the object.

To specify the *returning_clause*, you must have the `READ` or `SELECT` object privilege on the object.

If the `SQL92_SECURITY` initialization parameter is set to `TRUE` and the `UPDATE` operation references table columns, such as the columns in a *where_clause* or *returning_clause*, then you must have the `SELECT` object privilege on the object you want to update.

Syntax**update::=**

([DML table expression clause::=](#), [update set clause::=](#), [where clause::=](#),
[wait clause](#), [returning clause::=](#), [error logging clause::=](#), [from using clause::=](#))

DML table expression clause::=

([partition extension clause::=](#), [subquery::=](#)--part of SELECT, [subquery restriction clause::=](#),
[table collection expression::=](#))

partition extension clause::=

subquery_restriction_clause::=

table_collection_expression::=

update_set_clause::=

column_value_pairs::=

from_using_clause::=

where_clause::=**wait_clause****order_by_clause::=**See [order_by_clause::=](#)**returning_clause::=****error_logging_clause::=**

Semantics

hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

You can place a parallel hint immediately after the UPDATE keyword to parallelize both the underlying scan and UPDATE operations.

① See Also

- ["Hints"](#) for the syntax and description of hints
- *Oracle AI Database Concepts* for detailed information about parallel execution

DML_table_expression_clause

The ONLY clause applies only to views. Specify ONLY syntax if the view in the UPDATE clause is a view that belongs to a hierarchy and you do not want to update rows from any of its subviews.

① See Also

["Restrictions on the DML_table_expression_clause"](#) and ["Updating a Table: Examples"](#)

schema

Specify the schema containing the object to be updated. If you omit *schema*, then the database assumes the object is in your own schema.

table | view | materialized_view | subquery

Specify the name of the table, view, materialized view, or the columns returned by a subquery to be updated. Issuing an UPDATE statement against a table fires any UPDATE triggers associated with the table.

- If you specify *view*, then the database updates the base table of the view. You cannot update a view except with INSTEAD OF triggers if the defining query of the view contains one of the following constructs:
 - A set operator
 - A DISTINCT operator
 - An aggregate or analytic function
 - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
 - A collection expression in a SELECT list
 - A subquery in a SELECT list
 - A subquery designated WITH READ ONLY
 - A recursive WITH clause
 - Joins, with some exceptions, as documented in *Oracle AI Database Administrator's Guide*
- You cannot update more than one base table through a view.

- In addition, if the view was created with the `WITH CHECK OPTION`, then you can update the view only if the resulting data satisfies the view's defining query.
- If *table* or the base table of *view* contains one or more domain index columns, then this statement executes the appropriate indextype update routine.
- You cannot update rows in a read-only materialized view. If you update rows in a writable materialized view, then the database updates the rows from the underlying container table. However, the updates are overwritten at the next refresh operation. If you update rows in an updatable materialized view that is part of a materialized view group, then the database also updates the corresponding rows in the master table.

① See Also

- *Oracle AI Database Data Cartridge Developer's Guide* for more information on the indextype update routines
- [CREATE MATERIALIZED VIEW](#) for information on creating updatable materialized views

partition_extension_clause

Specify the name or partition key value of the partition or subpartition within *table* targeted for updates. You need not specify the partition name when updating values in a partitioned table. However in some cases specifying the partition name can be more efficient than a complicated *where_clause*.

① See Also

"[References to Partitioned Tables and Indexes](#)" and "[Updating a Partition: Example](#)"

dblink

Specify a complete or partial name of a database link to a remote database where the object is located. You can use a database link to update a remote object only if you are using the database distributed functionality.

If you omit *dblink*, then the database assumes the object is on the local database.

① Note

Starting with Oracle Database 12c Release 2 (12.2), the `UPDATE` statement accepts remote LOB locators as bind variables. Refer to the "Distributed LOBs" chapter in *Oracle AI Database SecureFiles and Large Objects Developer's Guide* for more information.

① See Also

"[References to Objects in Remote Databases](#)" for information on referring to database links

subquery_restriction_clause

Use the *subquery_restriction_clause* to restrict the subquery in one of the following ways:

WITH READ ONLY

Specify **WITH READ ONLY** to indicate that the table or view cannot be updated.

WITH CHECK OPTION

Specify **WITH CHECK OPTION** to indicate that the database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the **FROM** clause but not in subquery in the **WHERE** clause.

CONSTRAINT *constraint*

Specify the name of the **CHECK OPTION** constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form **SYS_Cn**, where **n** is an integer that makes the constraint name unique within the database.

① See Also

["Using the WITH CHECK OPTION Clause: Example"](#)

table_collection_expression

The *table_collection_expression* lets you inform Oracle that the value of *collection_expression* should be treated as a table for purposes of query and DML operations. The *collection_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the **TABLE** collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

① Note

In earlier releases of Oracle, when *collection_expression* was a subquery, *table_collection_expression* was expressed as **THE subquery**. That usage is now deprecated.

You can use a *table_collection_expression* to update rows in one table based on rows from another table. For example, you could roll up four quarterly sales tables into a yearly sales table.

t_alias

Specify a **correlation name** (alias) for the table, view, or subquery to be referenced elsewhere in the statement. This alias is required if the *DML_table_expression_clause* references any object type attributes or object type methods.

① See Also

["Correlated Update: Example"](#)

Restrictions on the *DML_table_expression_clause*

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base table of *view* contains any domain indexes marked IN_PROGRESS or FAILED.
- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.
- You cannot specify the *order_by_clause* in the subquery of the *DML_table_expression_clause*.
- If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the UPDATE statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE.

① See Also

[ALTER SESSION](#) for information on the SKIP_UNUSABLE_INDEXES session parameter

update_set_clause

The *update_set_clause* lets you set column values.

column

Specify the name of a column of the object that is to be updated. If you omit a column of the table from the *update_set_clause*, then the value of that column remains unchanged.

If *column* refers to a LOB object attribute, then you must first initialize it with a value of empty or null. You cannot update it with a literal. Also, if you are updating a LOB value using some method other than a direct UPDATE SQL statement, then you must first lock the row containing the LOB. See [for update_clause](#) for more information.

If *column* is a virtual column, you cannot specify it here. Rather, you must update the values from which the virtual column is derived.

If *column* is part of the partitioning key of a partitioned table, then UPDATE will fail if you change a value in the column that would move the row to a different partition or subpartition, unless you enable row movement. Refer to the *row_movement_clause* of [CREATE TABLE](#) or [ALTER TABLE](#).

In addition, if *column* is part of the partitioning key of a list-partitioned table, then UPDATE will fail if you specify a value for the column that does not already exist in the *partition_key_value* list of one of the partitions.

subquery

Specify a subquery that returns exactly one row for each row updated.

- If you specify only one column in the *update_set_clause*, then the subquery can return only one value.

- If you specify multiple columns in the *update_set_clause*, then the subquery must return as many values as you have specified columns.
- If the subquery returns no rows, then the column is assigned a null.
- If this *subquery* refers to remote objects, then the UPDATE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the *subquery* in the *DML_table_expression_clause* refers to any remote objects, then the UPDATE operation will run serially without notification.

You can use the *flashback_query_clause* within the subquery to update *table* with past data. Refer to the [flashback_query_clause](#) of SELECT for more information on this clause.

① See Also

- [SELECT](#) and "[Using Subqueries](#) "
- [parallel_clause](#) in the [CREATE TABLE](#) documentation

expr

Specify an expression that resolves to the new value assigned to the corresponding column.

① Note

[Expressions](#) for the syntax of *expr* and "[Updating an Object Table: Example](#)"

DEFAULT

Specify DEFAULT to set the column to the value previously specified as the default value for the column. If no default value for the corresponding column has been specified, then the database sets the column to null.

Restriction on Updating to Default Values

You cannot specify DEFAULT if you are updating a view.

You cannot use the DEFAULT clause in an UPDATE statement if the table that you are specifying has an Oracle Label Security policy enabled.

VALUE Clause

The VALUE clause lets you specify the entire row of an object table.

Restriction on the VALUE clause

You can specify this clause only for an object table.

① Note

If you insert string literals into a RAW column, then during subsequent queries, the database will perform a full table scan rather than using any index that might exist on the RAW column.

① See Also

["Updating an Object Table: Example"](#)

from_using_clause

Use this clause to filter the rows UPDATE changes, or to provide the values for the columns in the target table. Specify the join conditions in the *where_clause*. You can outer join source tables to the target table with (+). The target table cannot be the outer table in the join.

You can join many tables, views, and inline views. Specify the join conditions in the *where_clause* or use the *join_clause* to join these to each other with ANSI join syntax.

You can specify the same table in the *dml_table_expression_clause* and *from_clause*. When you do so they must have unique aliases.

Example: Update With Direct-Join

In this example, the join condition between table employees e and table jobs j determines which rows of employees are updated. The column jobs.max_salary supplies the new values for employees.salary:

```
UPDATE employees e
SET    e.salary = j.max_salary
FROM   jobs j
WHERE  j.job_id = e.job_id;
```

Direct joins for UPDATE have the same semantics and restrictions as SELECT in the *from_clause* and *where_clause*. The target table has the same restrictions as UPDATE. Triggers on the target table fire as normal.

Restrictions

- You cannot specify ANSI join syntax involving the *dml_table_expression_clause*. However, ANSI join syntax is allowed between the tables specified in the FROM clause. Right and full outer joins are not allowed.
- The UPDATE can change each row at most once. If the join condition results in the same row being updated more than once, the statement will raise an ORA-30926 error.
- You can only specify one table, view, or materialized view in *dml_table_expression_clause* when the *from_clause* is present.
- The left-hand side of *update_set_clause* must be a column from the *dml_table_expression_clause* and not from the *from_clause*.
- You can use a lateral view in the FROM clause, but it cannot reference a column from the update target. It may be outer-joined.
- Order by position is not allowed in the *order_by_clause*.
- UPDATE with *from_clause* supports *returning_clause* and *error_logging_clause*.
- Hint clause can be used to specify instructions to the optimizer for joins involving the *from_clause*.

where_clause

The *where_clause* lets you restrict the rows updated to those for which the specified *condition* is true. If you omit this clause, then the database updates all rows in the table or view. Refer to [Conditions](#) for the syntax of *condition*.

The *where_clause* determines the rows in which values are updated. If you do not specify the *where_clause*, then all rows are updated. For each row that satisfies the *where_clause*, the columns to the left of the equality operator (=) in the *update_set_clause* are set to the values of the corresponding expressions to the right of the operator. The expressions are evaluated as the row is updated.

wait_clause

The NOWAIT and WAIT clauses let you tell the database how to proceed if a transaction attempts to lock a row that is locked by another transaction.

Specify NOWAIT to rollback the DML statement immediately, if a lock exists.

Specify WAIT to instruct the database to wait *integer* SECONDS , MILLISECONDS, or MICROSECONDS. Seconds is the default.

Specify WAIT FOREVER to instruct the database to retain its default behavior of waiting for row locks indefinitely.

If you specify neither WAIT nor NOWAIT, then the database waits until the row is available and then returns the results of the SELECT statement.

order_by_clause

The following restrictions apply to the ORDER BY clause:

- When used in an analytic function, the *order_by_clause* must take an expression *expr*.
- The SIBLINGS keyword is not valid (it is relevant only in hierarchical queries)
- The *position* alias is invalid.

See [order_by_clause](#)

returning_clause

You can specify this clause for tables, views, and materialized views with a single base table.

When operating on a single row, a DML statement with a *returning_clause* can retrieve column values using the affected row, rowid, and REFS to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning_clause* returns values from expressions, rowids, and REFS involving the affected rows in bind arrays.

expr

Each item in the *expr* list must be a valid expression syntax.

INTO

The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data_item* list.

data_item

Each *data_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

Given columns *c1* and *c2* in a table, you can specify OLD for a column *c1*, (for example OLD *c1*). You can also specify OLD for a column referenced by a column expression (for example *c1*+OLD *c2*). When OLD is specified for a column, the column value before the update is returned. In the case of a column referenced by a column expression, what is returned is the result from evaluating the column expression using the column value before the update.

NEW can be explicitly specified for a column, or column referenced in an expression to return a column value after the update, or an expression result that uses the after update value of a column.

When OLD and NEW are both omitted for a column or an expression, the after update column value, or expression result computed using after update column values, is returned.

Restrictions

The following restrictions apply to the RETURNING clause:

- The *expr* is restricted as follows:
 - For UPDATE and DELETE statements each *expr* must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same *returning_clause*. For INSERT statements, each *expr* must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
 - Single-set aggregate function expressions cannot include the DISTINCT keyword.
- If the *expr* list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the *returning_clause* for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve LONG types with this clause.
- You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

Examples

Updating a Table: Examples

The following statement gives null commissions to all employees with the job SH_CLERK:

```
UPDATE employees
  SET commission_pct = NULL
  WHERE job_id = 'SH_CLERK';
```

The following statement promotes Douglas Grant to manager of Department 20 with a \$1,000 raise:

```
UPDATE employees SET
  job_id = 'SA_MAN', salary = salary + 1000, department_id = 120
  WHERE first_name||' '||last_name = 'Douglas Grant';
```

The following statement increases the salary of an employee in the employees table on the remote database:

```
UPDATE employees@remote
  SET salary = salary*1.1
  WHERE last_name = 'Baer';
```

The next example shows the following syntactic constructs of the UPDATE statement:

- Both forms of the *update_set_clause* together in a single statement
- A correlated subquery
- A *where_clause* to limit the updated rows

```
UPDATE employees a
  SET department_id =
    (SELECT department_id
     FROM departments
     WHERE location_id = '2100'),
    (salary, commission_pct) =
    (SELECT 1.1*AVG(salary), 1.5*AVG(commission_pct)
     FROM employees b
     WHERE a.department_id = b.department_id)
  WHERE department_id IN
    (SELECT department_id
     FROM departments
     WHERE location_id = 2900
       OR location_id = 2700);
```

The preceding UPDATE statement performs the following operations:

- Updates only those employees who work in Geneva or Munich (locations 2900 and 2700)
- Sets department_id for these employees to the department_id corresponding to Bombay (location_id 2100)
- Sets each employee's salary to 1.1 times the average salary of their department
- Sets each employee's commission to 1.5 times the average commission of their department

Updating a Partition: Example

The following example updates values in a single partition of the sales table:

```
UPDATE sales PARTITION (sales_q1_1999) s
  SET s.promo_id = 494
 WHERE amount_sold > 1000;
```

Updating an Object Table: Example

The following statement creates two object tables, `people_demo1` and `people_demo2`, of the `people_typ` object created in [Table Collections: Examples](#). The example shows how to update a row of `people_demo1` by selecting a row from `people_demo2`:

```
CREATE TABLE people_demo1 OF people_typ;

CREATE TABLE people_demo2 OF people_typ;

UPDATE people_demo1 p SET VALUE(p) =
  (SELECT VALUE(q) FROM people_demo2 q
   WHERE p.department_id = q.department_id)
 WHERE p.department_id = 10;
```

The example uses the `VALUE` object reference function in both the `SET` clause and the subquery.

Correlated Update: Example

For an example that uses a correlated subquery to update nested table rows, refer to "[Table Collections: Examples](#)".

Using the RETURNING Clause During UPDATE: Example

The following example returns values from the updated row and stores the result in PL/SQL variables `bnd1`, `bnd2`, `bnd3`:

```
UPDATE employees
  SET job_id = 'SA_MAN', salary = salary + 1000, department_id = 140
 WHERE last_name = 'Jones'
 RETURNING salary*0.25, last_name, department_id
        INTO :bnd1, :bnd2, :bnd3;
```

The following example shows that you can specify a single-set aggregate function in the expression of the returning clause:

```
UPDATE employees
  SET salary = salary * 1.1
 WHERE department_id = 100
 RETURNING SUM(salary) INTO :bnd1;
```

Update Using Direct Join: Example

The following example sets every employee's salary to the max salary for their job:

```
UPDATE hr.employees e
  SET e.salary = j.max_salary
 FROM hr.jobs j
 WHERE e.job_id = j.job_id;
```

Update Using WAIT Clause: Example

Note: `AUTOCOMMIT` is OFF.

Fork 2 sessions and run the commands alternatively in each as follows:

Session 1:

```
UPDATE hr.employees SET salary=100 WHERE employee_id=100;  
1 row updated.
```

Session 2:

```
UPDATE hr.employees SET commission_pct = commission_pct + 1  
WHERE employee_id = 100 WAIT 10 seconds;
```

The statement fails after waiting 10 seconds. Error messages:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",  
Description: "Lock held by a transaction to allow other transactions to wait  
for it") because it is currently held by another session. The resource being  
locked can be identified by 262148 ("usn<<16 | slot") and 1428 ("sequence")  
ORA-40097: Failure to acquire row lock, currently held by transaction ID 4.4.1428
```

Session 1:

```
COMMIT;  
Commit complete.
```

Update Using NOWAIT: Example

Session 1:

```
UPDATE hr.employees SET salary=100 WHERE employee_id=100;  
1 row updated.
```

Session 2:

```
UPDATE hr.employees SET commission_pct = commission_pct + 1  
WHERE employee_id = 100 NOWAIT;
```

The statement fails immediately on detecting a row lock. The following error messages appear:

```
ORA-00054: Failed to acquire a lock (Type: "TX", Name: "Transaction",  
Description: "Lock held by a transaction to allow other transactions to wait  
for it") because it is currently held by another session. The resource being  
locked can be identified by 262148 ("usn<<16 | slot") and 1428 ("sequence")  
ORA-40097: Failure to acquire row lock, currently held by transaction ID 4.4.1428
```

UPDATE END USER CONTEXT

Purpose

Use the UPDATE statement on the SYS.END_USER_CONTEXT view to set or modify the value of an attribute for a given context.

Prerequisites

You must have either UPDATE ANY END USER CONTEXT system privilege, or, have the UPDATE privilege granted through a data grant on SYS.END_USER_CONTEXT view for the specific context.

You must have the SELECT privilege to update a context attribute because updating a context attribute automatically instantiates the context if it has not been done already. In other words, when updating a new, unused context for the first time, both UPDATE and SELECT privileges are required.

Syntax

Semantics

- *owner*: owner of the context
- *name*: name of the context
- *attribute*: attribute in context
- *value*: the value to be set for the attribute

Restrictions

You cannot use bind variables to update end-user contexts.

Example

The following SQL statement sets the value for attribute *emp_id* in context *HR.HCM* to 3:

```
UPDATE END_USER_CONTEXT t SET t.CONTEXT.emp_id = 3
WHERE owner = 'HR' and name = 'HCM';
```

A

How to Read Syntax Diagrams

This appendix describes how to read syntax diagrams.

This reference presents Oracle SQL syntax in both graphic diagrams and in text (Backus-Naur Form—BNF). This appendix contains these sections:

- [Graphic Syntax Diagrams](#)
- [Backus-Naur Form Syntax](#)

Graphic Syntax Diagrams

Syntax diagrams are drawings that illustrate valid SQL syntax. To read a diagram, trace it from left to right, in the direction shown by the arrows.

Commands and other keywords appear in UPPERCASE inside rectangles. Type them exactly as shown in the rectangles. Parameters appear in lowercase inside ovals. Variables are used for the parameters. Punctuation, operators, delimiters, and terminators appear inside circles.

If the syntax diagram has more than one path, then you can choose any path. For example, in the following syntax you can specify either NOPARALLEL or PARALLEL:

parallel_clause::=

If you have the choice of more than one keyword, operator, or parameter, then your options appear in a vertical list. For example, in the following syntax diagram, you can specify one or more of the four parameters in the stack:

physical_attributes_clause::=

The following table shows parameters that appear in the syntax diagrams and provides examples of the values you might substitute for them in your statements:

Table A-1 Syntax Parameters

Parameter	Description	Examples
<i>table</i>	The substitution value must be the name of an object of the type specified by the parameter. For a list of all types of objects, see the section, " Schema Objects ".	employees
<i>c</i>	The substitution value must be a single character from your database character set.	T s
<i>'text'</i>	The substitution value must be a text string in single quotation marks. See the syntax description of <i>'text'</i> in " Text Literals ".	'Employee records'
<i>char</i>	The substitution value must be an expression of data type CHAR or VARCHAR2 or a character literal in single quotation marks.	last_name 'Smith'
<i>condition</i>	The substitution value must be a condition that evaluates to TRUE or FALSE. See the syntax description of <i>condition</i> in Conditions .	last_name > 'A'
<i>date</i> <i>d</i>	The substitution value must be a date constant or an expression of DATE data type.	TO_DATE('01-Jan-2002', 'DD-MON-YYYY')
<i>expr</i>	The substitution value can be an expression of any data type as defined in the syntax description of <i>expr</i> in " About SQL Expressions ".	salary + 1000
<i>integer</i>	The substitution value must be an integer as defined by the syntax description of integer in " Integer Literals ".	72
<i>number</i> <i>m</i> <i>n</i>	The substitution value must be an expression of NUMBER data type or a number constant as defined in the syntax description of <i>number</i> in " Numeric Literals ".	AVG(salary) 15 * 7
<i>raw</i>	The substitution value must be an expression of data type RAW.	HEXTORAW('7D')
<i>subquery</i>	The substitution value must be a SELECT statement that will be used in another SQL statement. See SELECT .	SELECT last_name FROM employees
<i>db_name</i>	The substitution value must be the name of a nondefault database in an embedded SQL program.	sales_db
<i>db_string</i>	The substitution value must be the database identification string for an Oracle Net database connection. For details, see the user's guide for your specific Oracle Net protocol.	—

Required Keywords and Parameters

Required keywords and parameters can appear singly or in a vertical list of alternatives. Single required keywords and parameters appear on the main path, which is the horizontal line you are currently traveling. In the following example, *library_name* is a required parameter:

drop_library::=

If there is a library named HQ_LIB, then, according to the diagram, the following statement is valid:

```
DROP LIBRARY hq_lib;
```

If multiple keywords or parameters appear in a vertical list that intersects the main path, then one of them is required. You must choose one of the keywords or parameters, but not necessarily the one that appears on the main path. In the following example, you must choose ALL, STANDBY, or NONE:

security_clause::=

Optional Keywords and Parameters

If keywords and parameters appear in a vertical list above the main path, then they are optional. In the following example, instead of traveling down a vertical line, you can continue along the main path:

deallocate_unused_clause::=***size_clause::=***

According to the diagrams, all of the following statements are valid:

```
DEALLOCATE UNUSED;
DEALLOCATE UNUSED KEEP 1000;
DEALLOCATE UNUSED KEEP 10G;
DEALLOCATE UNUSED 8T;
```

Syntax Loops

Loops let you repeat the syntax within them as many times as you like. In the following example, after choosing one value expression, you can go back repeatedly to choose another, separated by commas.

query_partition_clause::=

Multipart Diagrams

Read a multipart diagram as if all the main paths were joined end to end. The following example is a three-part diagram:

alter_java::=

According to the diagram, the following statement is valid:

```
ALTER JAVA SOURCE jsource_1 COMPILE;
```

Backus-Naur Form Syntax

Each graphic syntax diagram in this reference is followed by a link to a text description of the graphic. The text descriptions consist of a simple variant of Backus-Naur Form (BNF) that includes the following symbols and conventions:

Symbol or Convention	Meaning
[]	Brackets enclose optional items.
{ }	Braces enclose items only one of which is required.
	A vertical bar separates alternatives within brackets or braces.
...	Ellipsis points show that the preceding syntactic element can be repeated.
delimiters	Delimiters other than brackets, braces, vertical bars, and ellipses must be entered as shown.
boldface	Words appearing in boldface are keywords. They must be typed as shown. (Keywords are case-sensitive in some, but not all, operating systems.) Words that are not in boldface are placeholders for which you must substitute a name or value.

B

Automatic and Manual Locking Mechanisms During SQL Operations

This appendix describes mechanisms that lock data either automatically or as specified by the user during SQL statements. For a general discussion of locking mechanisms in the context of data concurrency and consistency, see *Oracle Database Concepts*.

This appendix contains the following sections:

- [Automatic Locks in DML Operations](#)
- [Automatic Locks in DDL Operations](#)
- [Manual Data Locking](#)
- [List of Nonblocking DDLs](#)

List of Nonblocking DDLs

Release 23

The following nonblocking DDLs are added in Release 23.3:

- alter table add column
- alter table set column unused
- alter table add constraint enable novalidate
- alter table drop constraint

Release 21

The following nonblocking DDLs are added in Release 21c:

- alter table modify default attributes tablespace
- alter table modify default attributes lob tablespace
- alter index modify default attributes tablespace
- alter table modify default attributes for partition tablespace
- alter table modify default attributes for partition lob tablespace
- alter index modify default attributes for partition tablespace

Release 12.2.0.2

List of Nonblocking DDLs Added in 12.2.0.2

- Alter table merge partition online
- alter table modify partition by .. online (to change the partitioning schema of a table)

Release 12.2.0.1**List of Nonblocking DDLs Added in 12.2.0.1**

- alter table split partition [subpartition] online
- alter table move online (move of a non-partitioned table)
- alter table modify partition by .. online (to convert a non-partitioned table to partitioned state)

Release 12.1

The following nonblocking DDLs are added as of Release 12.1. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

List of Nonblocking DDLs Added in 12.1

- drop index online
- alter index unusable online
- alter table move partition online
- alter table move subpartition online

List of Nonblocking DDLs Added in 12.1 that Downgrade to Blocking During Supplemental Logging

- alter table set unused column online
- alter table drop constraint online
- alter table modify column visible / invisible
- alter table add nullable column with default value

Release 11.2

The following nonblocking DDLs are added as of Release 11.2. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

List of Nonblocking DDLs Added in 11.2

- create index online
- alter index rebuild online
- alter index rebuild partition online
- alter index rebuild subpartition online
- alter index visible / novisible

List of Nonblocking DDLs Added in 11.2 that Downgrade to Blocking During Supplemental Logging

- alter table add column not null with default value
- alter table add constraint enable novalidate
- alter table modify constraint validate
- alter table add column (without any default)

Automatic Locks in DML Operations

The purpose of a DML lock, also called a **data lock**, is to guarantee the integrity of data being accessed concurrently by multiple users. For example, a DML lock can prevent multiple customers from buying the last copy of a book available from an online bookseller. DML locks prevent destructive interference of simultaneous conflicting DML or DDL operations.

DML statements automatically acquire locks at both the table level and the row level. In the sections that follow, the acronym in parentheses after each type of lock or lock mode is the abbreviation used in the Locks Monitor of Oracle Enterprise Manager. Enterprise Manager might display "TM" for any table lock, rather than indicate the mode of table lock (such as RS or SRX).

The types of row and table locks are summarized here. For a more complete discussion of the types of row and table locks, see *Oracle Database Concepts*.

Row Locks (TX)

A **row lock**, also called a **TX lock**, is a lock on a single row of a table. A transaction acquires a row lock for each row modified by one of the following statements: INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE. The row lock exists until the transaction commits or rolls back.

When a transaction obtains a row lock for a row, the transaction also acquires a table lock for the table in which the row resides. The table lock prevents conflicting DDL operations that would override data changes in a current transaction.

Table Locks (TM)

A transaction automatically acquires a table lock (**TM lock**) when a table is modified with the following statements: INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE. These DML operations require table locks to reserve DML access to the table on behalf of a transaction and to prevent DDL operations that would conflict with the transaction. You can explicitly obtain a table lock using the LOCK TABLE statement, as described in "[Manual Data Locking](#)".

A table lock can be held in any of the following modes:

- A **row share lock (RS)**, also called a **subshare table lock (SS)**, indicates that the transaction holding the lock on the table has locked rows in the table and intends to update them. An SS lock is the least restrictive mode of table lock, offering the highest degree of concurrency for a table.
- A **row exclusive lock (RX)**, also called a **subexclusive table lock (SX)**, indicates that the transaction holding the lock has updated table rows or issued SELECT ... FOR UPDATE. An SX lock allows other transactions to query, insert, update, delete, or lock rows concurrently in the same table. Therefore, SX locks allow multiple transactions to obtain simultaneous SX and SS locks for the same table.
- A **share table lock (S)** held by one transaction allows other transactions to query the table (without using SELECT ... FOR UPDATE) but allows updates only if a single transaction holds the share table lock. Multiple transactions may hold a share table lock concurrently, so holding this lock is not sufficient to ensure that a transaction can modify the table.
- A **share row exclusive table lock (SRX)**, also called a **share-subexclusive table lock (SSX)**, is more restrictive than a share table lock. Only one transaction at a time can acquire an SSX lock on a given table. An SSX lock held by a transaction allows other transactions to query the table (except for SELECT ... FOR UPDATE) but not to update the table.

- An **exclusive table lock (X)** is the most restrictive mode of table lock, allowing the transaction that holds the lock exclusive write access to the table. Only one transaction can obtain an X lock for a table.

① See Also

"[Manual Data Locking](#)"

Locks in DML Operations

Oracle Database automatically obtains row-level and table-level locks on behalf of DML operations. The type of operation determines the locking behavior. [Table B-1](#) summarizes the information in this section.

① Note

The implicit SX locks shown for the DML statements in [Table B-1](#) can sometimes be exclusive (X) locks for a short time owing to side effects from constraints.

Table B-1 Summary of Locks Obtained by DML Statements

SQL Statement	Row Locks	Table Lock Mode	RS	RX	S	SRX	X
SELECT ... FROM <i>table</i> ...	—	none	Y	Y	Y	Y	Y
INSERT INTO <i>table</i> ...	Yes	SX	Y	Y	N	N	N
UPDATE <i>table</i> ...	Yes	SX	Y¹	Y¹	N	N	N
MERGE INTO <i>table</i> ...	Yes	SX	Y	Y	N	N	N
DELETE FROM <i>table</i> ...	Yes	SX	Y¹	Y¹	N	N	N
SELECT ... FROM <i>table</i> FOR UPDATE OF ...	Yes	SX	Y¹	Y¹	N	N	N
LOCK TABLE <i>table</i> IN ...	—						
ROW SHARE MODE		SS	Y	Y	Y	Y	N
ROW EXCLUSIVE MODE		SX	Y	Y	N	N	N
SHARE MODE		S	Y	N	Y	N	N
SHARE ROW EXCLUSIVE MODE		SSX	Y	N	N	N	N
EXCLUSIVE MODE		X	N	N	N	N	N

¹ Yes, if no conflicting row locks are held by another transaction. Otherwise, waits occur.

Locks When Rows Are Queried

A query can be explicit, as in the SELECT statement, or implicit, as in most INSERT, MERGE, UPDATE, and DELETE statements. The only DML statement that does not necessarily include a query component is an INSERT statement with a VALUES clause. Because queries only read data, they are the SQL statements least likely to interfere with other SQL statements.

The following characteristics apply to a query *without* the FOR UPDATE clause:

- The query acquires no data locks. Therefore, other transactions can query and update a table being queried, including the specific rows being queried. Because queries without the FOR UPDATE clause do not acquire any data locks to block other operations, such queries are often referred to as **nonblocking queries**.
- The query does not have to wait for any data locks to be released. Therefore, the query can always proceed. An exception to this rule is that queries may have to wait for data locks in some very specific cases of pending distributed transactions.

Locks When Rows Are Modified

Some databases use a lock manager to maintain a list of locks in memory. Oracle Database, in contrast, stores lock information in the data block that contains the locked row. Each row lock affects only a single row.

Oracle Database uses a queuing mechanism for acquisition of row locks. If a transaction requires a row lock, and if the row is not already locked, then the transaction acquires a lock in the row's data block. The transaction itself has an entry in the **interested transaction list (ITL)** section of the block header. Each row modified by this transaction points to a copy of the transaction ID stored in the ITL. Thus, 100 rows in the same block modified by a single transaction require 100 row locks, but all 100 rows reference a single transaction ID.

When a transaction ends, the transaction ID remains in the ITL section of the data block header. If a new transaction wants to modify a row, then it uses the transaction ID to determine whether the lock is active. If the lock is active, then the session of the new transaction asks to be notified when the lock is released; otherwise, the new transaction acquires the lock.

The characteristics of INSERT, UPDATE, DELETE, and SELECT ... FOR UPDATE statements are as follows:

- A transaction containing a DML statement acquires exclusive row locks on the rows modified by the statement. Therefore, other transactions cannot update or delete the locked rows until the locking transaction either commits or rolls back.
- In addition to these row locks, a transaction containing a DML statement that modifies data also requires at least a subexclusive table lock (SX) on the table that contains the affected rows. If the transaction already holds an S, SRX, or X table lock for the table, which are more restrictive than an SX lock, then the SX lock is not needed and is not acquired. If the containing transaction already holds only an SS lock, however, then Oracle Database automatically converts the SS lock to an SX lock.
- A transaction that contains a DML statement does not require row locks on any rows selected by a subquery or an implicit query.

In the following sample UPDATE statement, the SELECT statement in parentheses is a subquery, whereas the WHERE a > 5 clause is an implicit query:

```
UPDATE t SET x = ( SELECT y FROM t2 WHERE t2.z = t.z ) WHERE a > 5;
```

A subquery or implicit query inside a DML statement is guaranteed to be consistent as of the start of the query and does not see the effects of the DML statement of which it forms a part.

- A query in a transaction can see the changes made by previous DML statements in the same transaction, but not the uncommitted changes of other transactions.

Oracle Database Concepts for information on locks in foreign keys

Automatic Locks in DDL Operations

A **data dictionary (DDL) lock** protects the definition of a schema object while it is acted upon or referred to by an ongoing DDL operation. For example, when a user creates a procedure, Oracle Database automatically acquires DDL locks for all schema objects referenced in the procedure definition. The DDL locks prevent these objects from being altered or dropped before procedure compilation is complete.

Oracle Database acquires a DDL lock automatically on behalf of any DDL transaction requiring it. Users cannot explicitly request DDL locks. Only individual schema objects that are modified or referenced are locked during DDL operations. The whole data dictionary is never locked.

DDL operations also acquire DML locks on the schema object to be modified.

Exclusive DDL Locks

An **exclusive DDL lock** prevents other session from obtaining a DDL or DML lock.

Most DDL operations require exclusive DDL locks to prevent destructive interference with other DDL operations that might modify or reference the same schema object. For example, a DROP TABLE operation is not allowed to drop a table while an ALTER TABLE operation is adding a column to it, and vice versa. However, a query against the table is not blocked.

Exclusive DDL locks last for the duration of DDL statement execution and automatic commit. During the acquisition of an exclusive DDL lock, if another DDL lock is already held on the schema object by another operation, then the acquisition waits until the older DDL lock is released and then proceeds.

Share DDL Locks

A **share DDL lock** for a resource prevents destructive interference with conflicting DDL operations, but allows data concurrency for similar DDL operations.

For example, when a CREATE PROCEDURE statement is run, the containing transaction acquires share DDL locks for all referenced tables. Other transactions can concurrently create procedures that reference the same tables and acquire concurrent share DDL locks on the same tables, but no transaction can acquire an exclusive DDL lock on any referenced table.

A share DDL lock lasts for the duration of DDL statement execution and automatic commit. Thus, a transaction holding a share DDL lock is guaranteed that the definition of the referenced schema object is constant for the duration of the transaction.

Breakable Parse Locks

A **parse lock** is held by a SQL statement or PL/SQL program unit for each schema object that it references. Parse locks are acquired so that the associated shared SQL area can be invalidated if a referenced object is altered or dropped. A parse lock is called a **breakable parse lock** because it does not disallow any DDL operation and can be broken to allow conflicting DDL operations.

A **parse lock** is acquired in the shared pool during the parse phase of SQL statement execution. The lock is held as long as the shared SQL area for that statement remains in the shared pool.

Manual Data Locking

Oracle Database always performs locking automatically to ensure data concurrency, data integrity, and statement-level read consistency. However, you can override the Oracle default locking mechanisms. This can be useful in situations such as the following:

- When your application requires consistent data for the duration of the transaction, not reflecting changes by other transactions, you can achieve transaction-level read consistency by using explicit locking, read-only transactions, serializable transactions, or by overriding default locking.
- When your application requires that a transaction have exclusive access to a resource so that the transaction does not have to wait for other transactions to complete, you can explicitly lock the data for the duration of the transaction.

You can override automatic locking at two levels:

- **Transaction.** You can override transaction-level locking with the following SQL statements:
 - SET TRANSACTION ISOLATION LEVEL
 - LOCK TABLE
 - SELECT ... FOR UPDATE

Locks acquired by these statements are released after the transaction commits or rolls back.

- **Session.** A session can set the required transaction isolate level with an ALTER SESSION SET ISOLATION LEVEL statement.

Note

When overriding Oracle default locking, the database administrator or application developer should ensure that data integrity is guaranteed, data concurrency is acceptable, and deadlocks are not possible or, if possible, are appropriately handled. For more information on these criteria, see *Oracle Database Concepts*.

C

Oracle and Standard SQL

This appendix declares Oracle's conformance to the SQL standards established by the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO).

The ISO SQL standard consists of eleven parts (SQL/Framework, SQL/Foundation, SQL/CLI, SQL/PSM, SQL/MED, SQL/OLB, SQL/Schemata, SQL/JRT, SQL/XML, SQL/MDA, and SQL/PGQ). The ANSI SQL standard consists of the same eleven parts.

The mandatory portion of SQL is known as Core SQL and is found in Part 2 (Foundation) and Part 11 (Schemata).

This appendix contains the following sections:

- [ANSI Standards](#)
- [ISO Standards](#)
- [Oracle Compliance to Core SQL](#)
- [Oracle Support for Optional Features of SQL/Foundation](#)
- [Oracle Compliance with SQL/CLI](#)
- [Oracle Compliance with SQL/PSM](#)
- [Oracle Compliance with SQL/MED](#)
- [Oracle Compliance with SQL/OLB](#)
- [Oracle Compliance with SQL/JRT](#)
- [Oracle Compliance with SQL/XML](#)
- [Oracle Compliance with SQL/MDA](#)
- [Oracle Compliance with SQL/PGQ](#)
- [Oracle Compliance with FIPS 127-2](#)
- [Oracle Extensions to Standard SQL](#)
- [Oracle Compliance with Older Standards](#)
- [Character Set Support](#)

ANSI Standards

The following documents of the American National Standards Institute (ANSI) relate to SQL:

- INCITS/ANSI/ISO/IEC 9075-1:2016, Information technology—Database languages—SQL—Part 1: Framework (SQL/Framework)
- INCITS/ANSI/ISO/IEC 9075-2:2016, Information technology—Database languages—SQL—Part 2: Foundation (SQL/Foundation)
- INCITS/ANSI/ISO/IEC 9075-3:2016, Information technology—Database languages—SQL—Part 3: Call-Level Interface (SQL/CLI)

- INCITS/ANSI/ISO/IEC 9075-4:2016, Information technology—Database languages—SQL—Part 4: Persistent Stored Modules (SQL/PSM)
- INCITS/ANSI/ISO/IEC 9075-9:2016, Information technology—Database languages—SQL—Part 9: Management of External Data (SQL/MED)
- INCITS/ANSI/ISO/IEC 9075-10:2016, Information technology—Database languages—SQL—Part 10: Object Language Bindings (SQL/OLB)
- INCITS/ANSI/ISO/IEC 9075-11:2016, Information technology—Database languages—SQL—Part 11: Information and Definition Schemas (SQL/Schemata)
- INCITS/ANSI/ISO/IEC 9075-13:2016, Information technology—Database languages—SQL—Part 13: SQL Routines and Types using the Java Programming Language (SQL/JRT)
- INCITS/ANSI/ISO/IEC 9075-14:2016, Information technology—Database languages—SQL—Part 14: XML-Related Specifications (SQL/XML)
- INCITS/ANSI/ISO/IEC 9075-15:2023, Information technology—Database language SQL—Part 15: Multidimensional arrays (SQL/MDA)
- INCITS/ANSI/ISO/IEC 9075-16:2023, Information technology—Database language SQL—Part 16: Property Graph Queries (SQL/PGQ)

These standards are identical to the corresponding ISO standards listed in the next section.

You can obtain a copy of ANSI standards from this address:

American National Standards Institute
25 West 43rd Street, fourth floor
New York, NY 10036 USA

Fax: +1.212.398.0023
Web site: <http://www.ansi.org/>

A subset of ANSI standards, including the SQL standard, are INCITS standards. You can obtain these from the InterNational Committee for Information Technology Standards (INCITS) at:

<http://www.incits.org/>

ISO Standards

The following documents of the International Organization for Standardization (ISO) relate to SQL:

- ISO/IEC 9075-1:2016, Information technology—Database languages—SQL—Part 1: Framework (SQL/Framework)
- ISO/IEC 9075-2:2016, Information technology—Database languages—SQL—Part 2: Foundation (SQL/Foundation)
- ISO/IEC 9075-3:2016, Information technology—Database languages—SQL—Part 3: Call-Level Interface (SQL/CLI)
- ISO/IEC 9075-4:2016, Information technology—Database languages—SQL—Part 4: Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9:2016, Information technology—Database languages—SQL—Part 9: Management of External Data (SQL/MED)
- ISO/IEC 9075-10:2016, Information technology—Database languages—SQL—Part 10: Object Language Bindings (SQL/OLB)

- ISO/IEC 9075-11:2016, Information technology—Database languages—SQL—Part 11: Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13:2016, Information technology—Database languages—SQL—Part 13: SQL Routines and Types using the Java Programming Language (SQL/JRT)
- ISO/IEC 9075-14:2016, Information technology—Database languages—SQL—Part 14: XML-Related Specifications (SQL/XML)

You can obtain a copy of ISO standards from this address:

Oracle Compliance to Core SQL

The ANSI and ISO SQL standards require conformance claims to state the type of conformance and the implemented facilities. The minimum claim of conformance is called Core SQL and is defined in Part 2, SQL/Foundation, and Part 11, SQL/Schemata, of the standard. The following products provide full or partial conformance with Core SQL as described in the tables that follow:

- Oracle Database server, release 12.2
- OTT (Oracle Type Translator), release 12.2
- Pro*C/C++, release 12.2
- Pro*COBOL, release 12.2

The SQL standards conformance features can be used either as a guide to portability, or as a guide to functionality. From the standpoint of portability, the user is interested in conformance to both the precise syntax and semantics of the standard feature. From the standpoint of functionality, the user is less concerned about the precise syntax and more concerned with issues of semantics. The tables in this appendix use the following terms regarding support for standard syntax and semantics:

- Full Support: The feature is supported with standard syntax and semantics.
- Partial Support: Some, but not all, of the standard syntax is supported; whatever is supported has standard semantics.
- Enhanced Support: The standard semantics is supported, as well as additional functionality.
- Equivalent Support: The standard semantics is supported using non-standard syntax.
- Similar Support: Neither the standard's syntax nor semantics are supported precisely, but similar functionality is provided.

Oracle's support for the features of Core SQL is listed in [Table C-1](#):

Table C-1 Oracle Support of Core SQL Features

Feature ID	Feature Support
E011, Numeric data types	Oracle fully supports this feature.
E021, Character data types	Oracle fully supports these subfeatures: - E021-01, CHARACTER data type - E021-07, Character concatenation - E021-08, UPPER and LOWER functions - E021-09, TRIM function - E021-10, Implicit casting among character data types Oracle partially supports these subfeatures: - E021-02, CHARACTER VARYING data type (Oracle does not distinguish a zero-length VARCHAR string from NULL) - E021-03, Character literals (Oracle regards the zero-length literal "" as being null) - E021-12, Character comparison (Oracle's rules for padding the shorter of two strings to be compared differs from the standard) Oracle has equivalent functionality for these subfeatures: - E021-04, CHARACTER_LENGTH function: use LENGTH function instead - E021-05, OCTET_LENGTH function: use LENGTHB function instead - E021-06, SUBSTRING function: use SUBSTR function instead - E021-11, POSITION function: use INSTR function instead
E031, Identifiers	Oracle supports this feature, with the following exceptions: - Oracle does not support the escape sequence to permit a double quote within a quoted identifier - A non-quoted identifier may not be equivalent to an Oracle reserved word (the list of Oracle reserved words differs from the standard's list) - A column name may not be ROWID, even as a quoted identifier Oracle extends this feature as follows: - An identifier may be up to 128 characters long - A non-quoted identifier may have dollar sign (\$) or pound sign (#)
E051, Basic query specification	Oracle fully supports the following subfeatures: - E051-01, SELECT DISTINCT - E051-02, GROUP BY clause - E051-04, GROUP BY can contain columns not in SELECT list - E051-05, SELECT list items can be renamed - E051-06, HAVING clause - E051-07, Qualified * in SELECT list Oracle partially supports the following subfeatures: - E051-08, Correlation names in FROM clause (Oracle supports correlation names, but not the optional AS keyword) Oracle has equivalent functionality for the following subfeature: - E051-09, Rename columns in the FROM clause (column names can be renamed in a subquery in the FROM clause)
E061, Basic predicates and search conditions	Oracle fully supports this feature, except that Oracle comparison of character strings differs from the standard as follows: In the standard, two character strings of unequal length are compared by either padding the shorter string with spaces or a fictitious character that is less than all actual characters. The decision on padding is made on the basis of the character set. In Oracle, the decision is based on whether the comparands are of fixed or varying length.

Table C-1 (Cont.) Oracle Support of Core SQL Features

Feature ID	Feature Support
E071, Basic query expressions	Oracle fully supports the following subfeatures: - E071-01, UNION DISTINCT table operator - E071-02, UNION ALL table operator - E071-05, Columns combined by table operators need not have exactly the same type - E071-06, table operators in subqueries Oracle has equivalent functionality for the following subfeature: - E071-03, EXCEPT DISTINCT table operator: Use MINUS instead of EXCEPT DISTINCT
E081, Basic privileges	Oracle fully supports all subfeatures of this feature, except E081-09, USAGE privileges. In the standard, the USAGE privilege permits the user to use domains, collations, character sets, transliterations, user-defined types and sequence generators. Oracle does not support domains or transliterations. No privileges are required to access collations and character sets. The Oracle privilege to use a user-defined type is EXECUTE. The Oracle privilege to use a sequence type is SELECT.
E091, Set functions	Oracle fully supports this feature.
E101, Basic data manipulation	Oracle fully supports this feature.
E111, Single row SELECT statement	Oracle fully supports this feature.
E121, Basic cursor support	Oracle fully supports the following subfeatures: - E121-02, ORDER BY columns need not be in SELECT list - E121-03, Value expressions in ORDER BY clause - E121-04, OPEN statement - E121-06, Positioned UPDATE statement - E121-07, Positioned DELETE statement - E121-08, CLOSE statement Oracle provides partial support for the following subfeatures: - E121-01, DECLARE CURSOR - fully supported, except for the FOR READ ONLY syntax - E121-10 FETCH statement, implicit NEXT - fully supported, except for the noise word FROM Oracle provides enhanced support for the following subfeature: - E121-17, WITH HOLD cursors (in the standard, a cursor is not held through a ROLLBACK, but Oracle does hold through ROLLBACK)
E131, Null value support	Oracle fully supports this feature, with this exception: In Oracle, a null of character type is indistinguishable from a zero-length character string.
E141, Basic integrity constraints	Oracle fully supports this feature.
E151, Transaction support	Oracle fully supports this feature.
E152, Basic SET TRANSACTION statement	Oracle fully supports this feature.

Table C-1 (Cont.) Oracle Support of Core SQL Features

Feature ID	Feature Support
E153, Updatable queries with subqueries	Oracle fully supports this feature.
E161, SQL comments using leading double minus	Oracle fully supports this feature.
E171, SQLSTATE support	Oracle fully supports this feature.
E182, Host language binding	Oracle fully supports this feature through Pro*C/C++ and Pro*COBOL
F021, Basic information schema	Oracle does not have any of the views in this feature. However, Oracle makes the same information available in other metadata views: • Instead of TABLES, use ALL_TABLES. • Instead of COLUMNS, use ALL_TAB_COLUMNS. • Instead of VIEWS, use ALL_VIEWS. However, Oracle's ALL_VIEWS does not display whether a user view was defined WITH CHECK OPTION or if it is updatable. To see whether a view has WITH CHECK OPTION, use ALL_CONSTRAINTS, with TABLE_NAME equal to the view name and look for CONSTRAINT_TYPE equal to 'V'. • Instead of TABLE_CONSTRAINTS, REFERENTIAL_CONSTRAINTS, and CHECK_CONSTRAINTS, use ALL_CONSTRAINTS. However, Oracle's ALL_CONSTRAINTS does not display whether a constraint is deferrable or initially deferred.
F031, Basic schema manipulation	Oracle fully supports these subfeatures: • F031-01, CREATE TABLE statement to create persistent base tables • F031-02, CREATE VIEW statement • F031-03, GRANT statement Oracle provides equivalent support for this subfeature: • F031-04, ALTER TABLE statement: ADD COLUMN clause (Oracle does not support the optional keyword COLUMN in this syntax. Also, Oracle requires the column definition to be enclosed in parentheses, unlike the standard.) Oracle does not support these subfeatures (because Oracle does not support the keyword RESTRICT): • F031-13, DROP TABLE statement: RESTRICT clause • F031-16, DROP VIEW statement: RESTRICT clause • F031-19, REVOKE statement: RESTRICT clause (Oracle DROP commands enhance the standard by invalidating dependent objects, so that they can be subsequently revalidated without user action, rather than either cascading all drops to dependent objects or prohibiting a drop if there is a dependent object.)
F041, Basic joined table	Oracle fully supports this feature.
F051, Basic date and time	Oracle fully supports this feature, except the following subfeatures are not supported: • F051-02, TIME data type • F051-07, LOCALTIME

Table C-1 (Cont.) Oracle Support of Core SQL Features

Feature ID	Feature Support
F081, UNION and EXCEPT in views	Oracle fully supports UNION in views.
F131, Grouped operations	Oracle fully supports this feature.
F181, Multiple module support	Oracle fully supports this feature.
F201, CAST function	Oracle fully supports this feature.
F221, Explicit defaults	Oracle's DEFAULT ON NULL capability in a column definition provides equivalent functionality for the INSERT statement though not for the UPDATE statement.
F261, CASE expressions	Oracle fully supports this feature.
F311, Schema definition statement	Oracle fully supports this feature.
F471, Scalar subquery values	Oracle fully supports this feature.
F481, Expanded null predicate	Oracle fully supports this feature.
F501, Feature and conformance views	Oracle does not support this feature.
F812, Basic flagging	Oracle has a flagger, but it flags SQL-92 compliance rather than SQL:2011 compliance.
S011, Distinct types	Distinct types are strongly typed scalar types. A distinct type can be emulated in Oracle using an object type with only one attribute. The standard's Information Schema view called USER_DEFINED_TYPES is equivalent to Oracle's metadata view ALL_TYPES.

Table C-1 (Cont.) Oracle Support of Core SQL Features

Feature ID	Feature Support
T321, Basic SQL-invoked routines	Oracle fully supports these subfeatures: - T321-03, function invocation - T321-04, CALL statement Oracle supports these subfeatures with syntactic differences: - T321-01, user-defined functions with no overloading - T321-02, user-defined procedures with no overloading The Oracle syntax for CREATE FUNCTION and CREATE PROCEDURE differs from the standard as follows: - In the standard, the mode of a parameter (IN, OUT, or INOUT) comes before the parameter name, whereas in Oracle it comes after the parameter name. - The standard uses INOUT, whereas Oracle uses IN OUT. - Oracle requires either IS or AS after the return type and before the definition of the routine body, while the standard lacks these keywords. - If the routine body is in C (for example), then the standard uses the keywords LANGUAGE C EXTERNAL NAME to name the routine, whereas Oracle uses LANGUAGE C NAME. - If the routine body is in SQL, then Oracle uses its proprietary procedural extension called PL/SQL. Oracle supports the following subfeature in PL/SQL but not in Oracle SQL: - T321-05, RETURN statement Oracle provides equivalent functionality for the following subfeatures: - T321-06, ROUTINES view: Use the ALL PROCEDURES metadata view. - T321-07, PARAMETERS view: Use the ALL_ARGUMENTS and ALL_METHOD_PARAMS metadata views.
T631, IN predicate with one list element	Oracle fully supports this feature.

Oracle Support for Optional Features of SQL/Foundation

Oracle's support for optional features of SQL/Foundation is listed in [Table C-2](#):

Table C-2 Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
B012, Embedded C	Oracle fully supports this feature.
B013, Embedded COBOL	Oracle fully supports this feature.
B021, Direct SQL	Oracle fully supports this feature, as SQL*Plus.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
B031, Basic dynamic SQL	Oracle supports dynamic SQL in two styles, documented in the embedded language manuals as "Oracle dynamic SQL" and "ANSI dynamic SQL." ANSI dynamic SQL is an implementation of the standard, with the following restrictions: • Oracle supports a subset of the descriptor items. • For <input using clause>, Oracle only supports <using input descriptor>. • For <output using clause>, Oracle only supports <into descriptor>. • Dynamic parameters are indicated by a colon followed by an identifier rather than a question mark. Oracle dynamic SQL is similar to standard dynamic SQL, with the following modifications: • Parameters are indicated by a colon followed by an identifier, instead of a question mark. • Oracle's DESCRIBE SELECT LIST FOR statement replaces the standard's DESCRIBE OUTPUT. • Oracle provides DECLARE STATEMENT if you want to declare a cursor using a dynamic SQL statement physically prior to the PREPARE statement that prepares the dynamic SQL statement.
B032, Extended dynamic SQL	In ANSI dynamic SQL, Oracle only implements the ability to declare global statements and global cursors from this feature; the rest of the feature is not supported. In Oracle dynamic SQL, Oracle's DESCRIBE BIND VARIABLES is equivalent to the standard's DESCRIBE INPUT; the rest of this feature is not supported.
B122, Routine language C	Oracle supports external routines written in C, though Oracle does not support the standard syntax for creating such routines.
B128, Routine language SQL	Oracle supports routines written in PL/SQL, which is Oracle's equivalent to the standard procedural language SQL/PSM.
F032, CASCADE drop behavior	In Oracle, a DROP command invalidates all of the dropped object's dependent objects. Invalidated objects are effectively unusable until the dropped object is redefined in such a way to allow successful recompilation of the invalidated object.
F033, ALTER TABLE statement: DROP COLUMN clause	Oracle provides a DROP COLUMN clause, but without the RESTRICT or CASCADE options found in the standard.
F034, Extended REVOKE statement	Oracle supports the following parts of this feature: • F034-01, REVOKE statement performed by other than the owner of a schema object • F034-03, REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION Oracle provides equivalent functionality for the following parts of this feature: CASCADE: In Oracle, a REVOKE invalidates all dependent objects, which become effectively unusable until the metadata is changed through subsequent CREATE and GRANT commands enabling the invalidated object to be successfully recompiled.
F052, Intervals and datetime arithmetic	Oracle only supports the INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND data types.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
F111, Isolations levels other than SERIALIZABLE	In addition to SERIALIZABLE, Oracle supports the READ COMMITTED isolation level.
F121, Basic diagnostics management	Much of the functionality of this feature is provided through the SQLCA in embedded languages.
F191, Referential delete actions	Oracle supports ON DELETE CASCADE and ON DELETE SET NULL.
F200, TRUNCATE TABLE	Oracle fully supports this feature, and extends it by permitting truncation of a table that references itself in a referential integrity constraint, and the ability to cascade to child tables with enabled ON DELETE CASCADE referential constraints.
F231, Privilege tables	Oracle makes this information available in the following metadata views: • Instead of TABLE_PRIVILEGES, use ALL_TAB_PRIVS. • Instead of COLUMN_PRIVILEGES, use ALL_COL_PRIVS. • Oracle does not support USAGE privileges so there is no equivalent to USAGE_PRIVILEGES.
F281, LIKE enhancements	Oracle fully supports this feature.
F291, UNIQUE predicate	The IS A SET condition may be used to test whether a multiset is a set; that is, each row is unique. Thus, the equivalent of UNIQUE <table subquery> is CAST (<table subquery> AS MULTISSET) IS A SET
F302, INTERSECT table operator	Syntactically, Oracle differs from the standard in that UNION, INTERSECT, and MINUS have the same precedence.
F312, MERGE statement	The Oracle MERGE statement is almost the same as the standard, with these exceptions: • Oracle does not support the optional AS keyword before a table alias. • Oracle does not support the ability to rename columns of the table specified in the USING clause with a parenthesized list of column names following the table alias. • Oracle does not support the <override clause>.
F314, MERGE statement with DELETE branch	Oracle has similar functionality, though in Oracle you must first update a row, after which you can delete it if the revised row meets a condition.
F321, User authorization	Oracle provides equivalent functionality for the following subfeatures: • Use SYS_CONTEXT ('USERENV', 'SESSION_USER') instead of SESSION_USER • Use SYS_CONTEXT ('USERENV', 'CURRENT_USER') instead of CURRENT_USER Oracle does not support the following subfeatures: • SYSTEM_USER • SET SESSION AUTHORIZATION statement
F341, Usage tables	Oracle makes this information available in the views ALL_DEPENDENCIES, DBA_DEPENDENCIES, and USER_DEPENDENCIES.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
F381, Extended schema manipulation	Oracle fully supports the following element of this feature: - Oracle supports the standard syntax to add a table constraint using ALTER TABLE. - Oracle partially supports the following element of this feature: Oracle supports the standard syntax to drop a table constraint, except that Oracle does not support RESTRICT. - Oracle provides equivalent functionality for the following element of this feature: - To alter the default value of a column, use the MODIFY option of ALTER TABLE. - Oracle does not support the following parts of this feature: - DROP SCHEMA statement - ALTER ROUTINE statement
F382, Alter column data type	Oracle supports this functionality, though with non-standard syntax. As an extension to the standard, Oracle allows you to reduce the size or precision of a column.
F383, Set column not null clause	Oracle provides equivalent functionality for the two subfeatures of this feature: - To add a NOT NULL constraint to an existing column, use ALTER TABLE ... MODIFY - To drop a NOT NULL constraint, use ALTER TABLE to drop the constraint by name
F384, Drop identity property clause	Oracle provides equivalent functionality using ALTER TABLE ... MODIFY (... DROP IDENTITY)
F386, Set identity column generation clause	Oracle provides equivalent functionality. Oracle's syntax and semantics are the same as the standard, with this exception: Oracle does not support RESTART; use START WITH instead. When restarting an identity column, the values of the other parameters for the identity column are reset to their defaults unless explicitly set in the ALTER TABLE statement. Oracle's START WITH LIMIT VALUE option is an extension on the standard.
F391, Long identifiers	Oracle supports identifiers up to 128 characters in length.
F393, Unicode escapes in literals	The Oracle UNISTR function supports numeric escape sequences for all Unicode characters.
F394, Optional normal form specification	This feature adds the keywords NFC, NFD, NFKC, and NKD to the NORMALIZE function and the IS NORMAL predicate. Without these keywords, NFC is the default (see Feature T061, UCS support). Oracle supports all four normalization forms, with nonstandard syntax, as follows: - For NFC, use COMPOSE - For NFD, use DECOMPOSE with the CANONICAL option - For NFKD, use DECOMPOSE with the COMPATIBILITY option - For NFKC, use DECOMPOSE with the CANONICAL option followed by COMPOSE Oracle does not support the IS NORMAL predicate.
F401, Extended joined table	Oracle supports FULL outer joins, CROSS joins, and NATURAL joins.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
F402, Named column joins for LOBs, arrays and multisets	Oracle supports named column joins for columns whose declared type is nested table. Oracle does not support named column joins for LOBs or arrays.
F403, Partitioned join tables	Oracle supports this feature, except with FULL outer joins.
F411, Time zone specification	Oracle fully supports <code>TIMESTAMP WITH TIME ZONE</code> , but does not support <code>TIME WITH TIME ZONE</code> .
F421, National character	Oracle fully supports this feature.
F431, Read-only scrollable cursors	Oracle fully supports this feature.
F441, Extended set function support	Oracle supports the following parts of this feature: • The ability in the WHERE clause to reference a column that is defined using an aggregate, either in a view or an inline view • COUNT without DISTINCT of an expression • Aggregates that reference columns that are outer references with respect to the aggregating query. However, Oracle defines the aggregating query as the innermost query containing the aggregate, rather than the innermost query that defines a range variable referenced in the aggregate.
F442, Mixed column references in set functions	Oracle fully supports this feature.
F461, Named character sets	Oracle supports many character sets with Oracle-defined names. Oracle does not support any other aspect of this feature.
F491, Constraint management	Oracle fully supports this feature.
F492, Optional table constraint enforcement	ENFORCED in the standard is equivalent to ENABLE VALIDATE in Oracle. NOT ENFORCED in the standard is equivalent to DISABLE NOVALIDATE in Oracle. Other combinations of the ENABLE DISABLE, VALIDATE NOVALIDATE, and RELY NORELY options are extensions of the standard.
F521, Assertions	Oracle supports this feature, with the restrictions listed in CREATE ASSERTION. Oracle extends this feature with universal expression ALL . . . SATISFY syntax.
F531, Temporary tables	Oracle supports GLOBAL TEMPORARY tables.
F555, Enhanced seconds precision	Oracle provides enhanced support for this feature, supporting up to 9 places after the decimal point.
F561, Full value expressions	Oracle fully supports this feature.
F571, Truth value tests	Oracle's LNNVL function is equivalent to the standard's IS NOT TRUE predicate.
F591, Derived tables	Oracle supports <derived table>, with the exception of: • Oracle does not support the optional AS keyword before a table alias. • Oracle does not support <derived column list>.
F641, Row and table constructors	In Oracle, a row constructor may be used in an equality or inequality comparison with another row constructor or with a subquery. Oracle does not support anything else in this feature.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
F690, Collation support	Oracle's NLSSORT function may be used to change the collation of character expressions.
F693, SQL-sessions and client module collations	To set a session collation, use ALTER SESSION SET NLS_COMP = 'LINGUISTIC' and also set NLS_SORT to your desired collation. Oracle does not support client module collations.
F695, Translation support	The Oracle CONVERT function can convert between the database character set and the national character set. For other character sets, store the data in the RAW data type and use the PL/SQL package function UTL_RAW.CONVERT. Oracle does not provide the ability to add or drop character set conversions.
F721, Deferrable constraints	Oracle fully supports this feature.
F731, INSERT column privileges	Oracle fully supports this feature.
F761, Session management	Oracle provides the following equivalents for elements of this feature: - The equivalent to the standard's SET SESSION CHARACTERISTICS AS TRANSACTION SERIALIZABLE is ALTER SESSION SET ISOLATION_LEVEL = SERIALIZABLE. - The equivalent to the standard's SET SCHEMA is ALTER SESSION SET CURRENT_SCHEMA. - The equivalent to the standard's SET COLLATION is ALTER SESSION SET NLS_SORT.
F763, CURRENT_SCHEMA	Oracle's equivalent is SYS_CONTEXT ('USERENV' , 'CURRENT_SCHEMA')
F771, Connection management	Oracle's CONNECT statement provides the same functionality as the standard's CONNECT statement, though with different syntax. Instead of using the standard's SET CONNECTION, Oracle provides the AT clause to indicate which connection a SQL statement should be performed on. Oracle embedded languages let you disconnect from a connection by using the RELEASE option of either COMMIT or ROLLBACK.
F781, Self-referencing operations	Oracle fully supports this feature.
F801, Full set function	Oracle fully supports this feature.
F831, Full cursor update	Oracle supports the combination of FOR UPDATE and ORDER BY clauses in a query.
F841, LIKE_REGEX predicate	Oracle's equivalent is REGEXP_LIKE. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.
F842, OCCURRENCES_REGEX function	Oracle's equivalent is REGEXP_COUNT. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.
F843, POSITION_REGEX function	Oracle's equivalent is REGEXP_INSTR. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
F844, SUBSTRING_REGEX function	Oracle's equivalent is REGEXP_SUBSTR. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.
F845, TRANSLATE_REGEX function	Oracle's equivalent is REGEXP_REPLACE. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.
F850, Top-level <order by clause> in <query expression>	Oracle fully supports this feature.
F851, <order by clause> in subqueries	Oracle fully supports this feature.
F852, Top-level <order by clause> in views	Oracle fully supports this feature.
F855, Nested <order by clause> in <query expression>	Oracle fully supports this feature.
F856, Nested <fetch first clause> in <query expression>	Oracle fully supports this feature.
F857, Top-level <fetch first clause> in a <query expression>	Oracle fully supports this feature.
F858, <fetch first clause> in subqueries	Oracle fully supports this feature.
F859, Top-level <fetch first clause> in views	Oracle fully supports this feature.
F860, Dynamic <fetch first row count> in <fetch first clause>	Oracle fully supports this feature.
F861, Top-level <result offset clause> in <query expression>	Oracle fully supports this feature.
F862, <result offset clause> in subqueries	Oracle fully supports this feature.
F863, Nested <result offset clause> in <query expression>	Oracle fully supports this feature.
F864, Top-level <result offset clause> in views	Oracle fully supports this feature.
F865, Dynamic <offset row count> in <result offset clause>	Oracle fully supports this feature.
F866, FETCH FIRST clause: PERCENT option	Oracle fully supports this feature.
F867, FETCH FIRST clause: WITH TIES option	Oracle fully supports this feature.
R010, Row pattern recognition: FROM clause	Oracle fully supports this feature.
S023, Basic structured types	Oracle's object types are equivalent to structured types in the standard.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
S024, Enhanced structured types	Oracle's syntax is non-standard, but provides equivalents for the following: • NOT INSTANTIABLE • STATIC methods • RELATIVE, MAP, and STATE orderings. The keyword in Oracle for RELATIVE orderings is ORDER. There is no keyword for STATE orderings (this is the default, if no other ordering is defined). Unlike the standard, Oracle does not support EQUALS ONLY on non-STATE orderings. (See also Feature S251, User-defined orderings.) • SELF AS RESULT in the signature of constructor methods
S025, Final structured types	Oracle's final object types are equivalent to final structured types in the standard.
S026, Self-referencing structured types	In Oracle, an object type OT may have a reference that references OT.
S041, Basic reference types	Oracle's reference types are equivalent to reference types in the standard. To dereference a reference, dot notation is used, instead of - > as in the standard.
S043, Enhanced reference types	Oracle supports the following elements of this feature: • Deref operator to return the object referenced by a reference • SCOPE clause as a constraint on columns of tables or materialized views • Adding and dropping the scope of a column • References that are either system-generated or derived from the primary key (but not from any other list of columns, nor from a list of attributes of the type)
S051, Create table of type	Oracle's object tables are equivalent to tables of structured type in the standard.
S081, Subtables	Oracle supports hierarchies of object views, but not of object base tables. To emulate a hierarchy of base tables, create a hierarchy of views on those base tables.
S091, Basic array support	Oracle VARRAY types are equivalent to array types in the standard. However, Oracle does not support storage of arrays of LOBs. To access a single element of an array using a subscript, you must use PL/SQL. Oracle supports the following aspects of this feature with nonstandard syntax: • To construct an instance of varray type, including an empty array, use the varray type constructor. • To unnest a varray in the FROM clause, use the TABLE operator. • To get the cardinality of a varray, use the COUNT method in PL/SQL.
S092, Arrays of user-defined types	Oracle supports VARRAYs of object types.
S094, Arrays of reference types	Oracle supports VARRAYs of references.
S095, Array constructors by query	Oracle supports this using CAST (MULTISET (SELECT ...) AS varray_type). The ability to order the elements of the array using ORDER BY is not supported.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
S097, Array element assignment	In PL/SQL, you can assign to array elements, using syntax that is similar to the standard (SQL/PSM).
S098, ARRAY_AGG	Oracle does not have an aggregate that results in a varray. Instead, the COLLECT aggregate may be used to create a multiset, which can be cast to an array of the element type.
S111, ONLY in query expressions	Oracle supports the ONLY clause for view hierarchies; Oracle does not support hierarchies of base tables.
S151, Type predicate	Oracle fully supports this feature.
S161, Subtype treatment	Oracle fully supports this feature.
S162, Subtype treatment for references	Supported, with a minor syntactic difference: The standard requires parentheses around the referenced type's name; Oracle does not support parentheses in this position.
S201, SQL-invoked routines on arrays	PL/SQL provides the ability to pass arrays as parameters and return arrays as the result of functions. Procedures and functions written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator (OTT).
S202, SQL-invoked routines on multisets	A PL/SQL routine may have nested tables as parameters, and may return a nested table. Routines written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator.
S232, Array locators	Oracle Type Translator supports descriptors for arrays, which achieve the same purpose as locators.
S233, Multiset locators	Oracle supports locators for nested tables.
S241, Transform functions	The Oracle Type Translator provides the same capability as transforms.
S251, User-defined orderings	Oracle's object type ordering capabilities correspond to the standard's capabilities as follows: • Oracle's MAP ordering corresponds to the standard's ORDER FULL BY MAP ordering. • Oracle's ORDER ordering corresponds to the standard's ORDER FULL BY RELATIVE ordering. • If an Oracle object type has neither MAP nor ORDER declared, then this corresponds to EQUALS ONLY BY STATE in the standard. • Oracle does not have unordered object types; you can alter the ordering but you cannot drop it.
S261, Specified type method	The GetTypeName method of the ANYDATA type may be used to learn the name of a type.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
S271, Basic multiset support	Multisets in the standard are supported as nested table types in Oracle. The Oracle nested table data type based on a scalar type <i>ST</i> is equivalent, in standard terminology, to a multiset of rows having a single field of type <i>ST</i> and named <i>column_value</i>. The Oracle nested table type based on an object type is equivalent to a multiset of structured type in the standard. Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets: • The <i>CARDINALITY</i> function • The <i>SET</i> function • The <i>MEMBER</i> predicate • The <i>IS A SET</i> predicate • The <i>COLLECT</i> aggregate All other aspects of this feature are supported with non-standard syntax, as follows: • To create an empty multiset, denoted <i>MULTISET []</i> in the standard, use an empty constructor of the nested table type. • To obtain the sole element of a multiset with one element, denoted <i>ELEMENT (<multiset value expression>)</i> in the standard, use a scalar subquery to select the single element from the nested table. • To construct a multiset by enumeration, use the constructor of the nested table type. • To construct a multiset by query, use <i>CAST</i> with a multiset argument, casting to the nested table type. • To unnest a multiset, use the <i>TABLE</i> operator in the <i>FROM</i> clause.
S272, Multisets of user-defined types	Oracle's nested table type permits a multiset of structured types. Oracle does not have distinct types, so a multiset of distinct types is not supported.
S274, Multisets of reference types	A nested table type can have one or more columns of reference type.
S275, Advanced multiset support	Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets: • The <i>MULTISET UNION</i>, <i>MULTISET INTERSECTION</i>, and <i>MULTISET EXCEPT</i> operators • The <i>SUBMULTISET</i> predicate • <i>=</i> and <i><></i> predicates Oracle does not support the <i>FUSION</i> or <i>INTERSECTION</i> aggregates.
S281, Nested collection types	Oracle permits nesting of its collection types (varray and nested table).
S401, Distinct types based on array types	Oracle's varray types are strongly typed.
S403, <i>ARRAY_MAX_CARDINALITY</i>	In PL/SQL, the <i>LIMIT</i> method of a varray returns its maximum cardinality.
S404, <i>TRIM_ARRAY</i>	In PL/SQL, the <i>TRIM</i> method of a varray can be used to trim the varray.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T041, Basic LOB data type support	Oracle supports the following aspects of this feature: • The keywords BLOB, CLOB, and NCLOB • Concatenation, UPPER, LOWER on CLOBs Oracle provides equivalent support for the following aspects of this feature: • Use INSTR instead of POSITION. • Use LENGTH instead of CHAR_LENGTH. Oracle does not support the following aspects of this feature: • The keywords BINARY LARGE OBJECT, CHARACTER LARGE OBJECT, and NATIONAL CHARACTER LARGE OBJECT as synonyms for BLOB, CLOB, and NCLOB, respectively • <binary string literal> • The ability to specify an upper bound on the length of a BLOB or CLOB • Concatenation of BLOBs
T042, Extended LOB support	Oracle fully supports the following element of this feature: • TRIM function on a CLOB argument Oracle provides equivalent functionality for the following elements of this feature: • BLOB and CLOB substring, supported using SUBSTR • SIMILAR predicate, supported using REGEXP_LIKE to perform pattern matching with a Perl-like syntax The following elements of this feature are not supported: • Comparison predicates with BLOB or CLOB operands • CAST with a BLOB or CLOB operand • OVERLAY (This may be emulated using SUBSTR and string concatenation.) • LIKE predicate with BLOB or CLOB operands
T051, Row types	Oracle object types can be used in place of the standard's row types.
T061, UCS support	Oracle provides equivalent functionality for the following elements of this feature: • Oracle supports the keyword CHAR instead of CHARACTERS, and BYTE instead of OCTETS, in a character data type declaration. • The Oracle COMPOSE function is equivalent to the standard's NORMALIZE function. Oracle does not support the IS NORMALIZED predicate.
T071, BIGINT data type	On many implementations, BIGINT refers to a binary integer type with 64 bits, which supports almost 19 decimal digits. The Oracle NUMBER type supports 39 decimal digits.
T111, Updatable joins, unions and columns	Oracle's updatable join views are similar to the standard's updatable join capabilities. Unlike the standard, Oracle does not require an updatable join view to display the strong candidate key in the SELECT list. Although an updatable join view might have more than one key-preserved table, only one of them may be modified using an UPDATE or DELETE, unlike the standard, which modifies all key-preserved tables of an updatable join.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T121, WITH (excluding RECURSIVE) in query expression	Oracle fully supports this feature.
T122, WITH (excluding RECURSIVE) in subquery	Oracle fully supports this feature.
T131, Recursive query	Oracle supports the use of a WITH clause element that references itself, but without the RECURSIVE keyword. Alternatively, Oracle's START WITH and CONNECT BY clauses can be used to perform many recursive queries.
T132, Recursive query in subquery	Oracle supports the use of a WITH clause element that references itself, but without the RECURSIVE keyword. Alternatively, Oracle's START WITH and CONNECT BY clauses can be used to perform many recursive queries.
T141, SIMILAR predicate	Oracle provides REGEXP_LIKE for pattern matching with a Perl-like syntax.
T172, AS subquery clause in table definition	Oracle's AS subquery feature of CREATE TABLE has substantially the same functionality as the standard, though there are some syntactic differences.
T174, Identity columns	Oracle supports this feature, with the following syntactic differences: • Oracle uses NOMINVALUE and NOMAXVALUE instead of the standard's NO MINVALUE and NO MAXVALUE. • To restart an identity column, in an ALTER TABLE MODIFY statement, use START WITH LIMIT VALUE to restart at the highest value (for an increasing identity column) or the lowest value (for a decreasing identity column); use START WITH number to restart at a specific number. GENERATED BY DEFAULT ON NULL is an Oracle extension.
T175, Generated columns	Oracle supports this feature, with the following restrictions: • Generated columns are not supported in temporary tables. • The data type of a generated column may not be LOB or XML.
T176, Sequence generator support	Oracle's sequences have the same capabilities as the standard's, though with different syntax.
T178, Identity columns: simple restart option	Oracle's START WITH LIMIT VALUE is the same as the standard's simple restart if the identity column has not cycled.
T180, System-versioned tables	Oracle's Flashback capability is substantially the same as the standard's system-versioned tables. Some key differences are: • In Oracle you do not need to designate particular tables for journaling; all tables are journaled. • In Oracle, LOB columns need to be individually designated for journaling, because of the potential for large amounts of data. The standard has no analogous provision. • In Oracle you need a privilege in order to read historical data. • In the standard, journaled tables have columns to record the start and end timestamps for the row. In Oracle, this is provided through pseudocolumns.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T181, Application-time period tables	Oracle supports the following elements of this feature: • Application-time period definition during CREATE TABLE • Adding and dropping an application-time period definition using ALTER TABLE with a minor syntactic difference: Oracle requires parentheses around the period specification; the standard does not support parentheses in this position. Oracle extends this feature: • With the ability to have more than one application-time period per table. • By making the start time and end time columns optional. In this case, Oracle will create these columns implicitly. • By allowing NULL for the start time column to indicate that the row is considered valid for any point in time before the value of the end time column. • By allowing NULL for the end time column to indicate that the row is considered valid for any point in time on or after the value of the start time column. • By querying an application-time period table using the flashback query options VERSIONS PERIOD FOR and AS OF PERIOD FOR.
T201, Comparable data types for referential constraints	Oracle fully supports this feature.
T211, Basic trigger capability	Oracle's triggers differ from the standard as follows: • Oracle does not provide the optional syntax FOR EACH STATEMENT for the default case, the statement trigger. • Oracle does not support OLD TABLE and NEW TABLE; the transition tables specified in the standard (the multiset of before and after images of affected rows) are not available. • The trigger body is written in PL/SQL, which is functionally equivalent to the standard's procedural language PSM, but not the same. • In the trigger body, the new and old transition variables are referenced beginning with a colon. • Oracle's row triggers are executed as the row is processed, instead of buffering them and executing all of them after processing all rows. The standard's semantics are deterministic, but Oracle's in-flight row triggers are more performant. • Oracle's before-row and before-statement triggers can perform DML statements, which is forbidden in the standard. However, Oracle's after-row statements cannot perform DML, while it is permitted in the standard. • When multiple triggers apply, the standard says they are executed in order of definition. In Oracle the execution order is nondeterministic, unless specified using FOLLOWS. • Oracle uses the system privileges CREATE TRIGGER and CREATE ANY TRIGGER to regulate creation of triggers, instead of the standard's TRIGGER privilege, which is a table privilege.
T212, Enhanced trigger capability	This feature permits statements triggers, which Oracle supports, as described for feature T211, Basic trigger capability.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T213, INSTEAD OF triggers	Oracle supports INSTEAD OF triggers on views, with syntax and semantics agreeing with the standard except as noted for feature T211, Basic trigger capability. Oracle permits an INSTEAD OF trigger on a view that specified WITH CHECK OPTION, unlike the standard.
T241, START TRANSACTION statement	Oracle's SET TRANSACTION statement starts a transaction making it equivalent to the standard's START TRANSACTION rather than the standard's SET TRANSACTION. Oracle's READ ONLY transactions are at SERIALIZABLE isolation level.
T271, Savepoints	Oracle supports this feature, except: • Oracle does not support RELEASE SAVEPOINT. • Oracle does not support savepoint levels.
T285, Enhanced derived column names	This feature pertains only to derived columns in a SELECT list with no column alias and consisting of a SQL parameter reference. In that case, the column name defaults to the parameter name, the same as in the standard.
T323, Explicit security for external routines	The Oracle syntax AUTHID { CURRENT USER DEFINER } when used when creating an external function, procedure, or package is equivalent to the standard's EXTERNAL SECURITY { DEFINER INVOKER }.
T324, Explicit security for SQL routines	Oracle's syntax AUTHID { CURRENT USER DEFINER } when used when creating a PL/SQL function, procedure, or package is equivalent to the standard's SQL SECURITY { DEFINER INVOKER }.
T325, Qualified SQL parameter reference	PL/SQL supports the use of a routine name to qualify a parameter name.
T326, Table functions	Oracle provides equivalents for the following elements of this feature: • <multiset value constructor by query> is supported using CAST (MULTISET (<query expression>) AS <nested table type>) • <table function derived table> is supported using the TABLE operator in the FROM clause with a varray or nested table as the argument • <collection value expression> is equivalent to an Oracle expression resulting in a varray or nested table • <returns table type> is equivalent to a PL/SQL function that returns a nested table
T331, Basic roles	Oracle supports this feature, except for REVOKE ADMIN OPTION FOR <role name>.
T341, Overloading of SQL-invoked functions and procedures	Oracle supports overloading of functions and procedures. However, the rules for handling certain data type combinations are not the same as the standard. For example, the standard permits the coexistence of two functions of the same name differing only in the numeric types of the arguments, whereas Oracle does not permit this.
T351, Bracketed comments	Oracle fully supports this feature.
T431, Extended grouping capabilities	Oracle fully supports this feature.
T432, Nested and concatenated GROUPING SETS	Oracle supports concatenated GROUPING SETS, but not nested GROUPING SETS.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T433, Multiargument function GROUPING	The Oracle GROUP_ID function can be used to conveniently distinguish groups in a grouped query, serving the same purpose as the standard multiargument GROUPING function.
T441, ABS and MOD functions	Oracle supports the ABS function. Oracle's MOD function is similar to the standard, though the behavior is different if the two arguments are of opposite sign.
T471, Result sets return value	PL/SQL ref cursors provide all the functionality of the standard's result set cursors.
T491, LATERAL derived tables	Oracle fully supports this feature.
T501, Enhanced EXISTS predicate	Oracle fully supports this feature.
T511, Transaction counts	Oracle supports the count of transactions committed and rolled back via the system views V\$STATNAME and V\$SESSTAT.
T521, Named arguments in CALL statement	Oracle fully supports this feature.
T522, Default values for IN parameters of SQL-invoked procedures	Oracle fully supports this feature.
T524, Named arguments in routine invocations other than a CALL statement	Oracle fully supports this feature.
T525, Default values for parameters of SQL-invoked functions	Oracle fully supports this feature.
T571, Array-returning external SQL-invoked function	Oracle table functions returning a varray can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause.
T572, Multiset-returning external SQL-invoked function	Oracle table functions returning a nested table can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause. In the body of the function, use the OCITable interface. The function must be invoked within the TABLE operator in the FROM clause.
T581, Regular expressions substring functions	Oracle provides the REGEXP_SUBSTR function to perform substring operations using regular expression matching.
T591, UNIQUE constraints of possibly null columns	Oracle permits a UNIQUE constraint on one or more nullable columns. If the UNIQUE constraint is on a single column, then the semantics are the same as the standard (the constraint permits any number of rows that are null in the designated column). If the UNIQUE constraint is on two or more columns, then the semantics are nonstandard. Oracle permits any number of rows that are null in all the designated columns. Unlike the standard, if a row is non-null in at least one of the designated columns, then another row having the same values in the non-null columns of the constraint is a constraint violation and not permitted.
T611, Elementary OLAP operations	Oracle fully supports this feature, except that DISTINCT is only supported in conjunction with window partitioning but not with window framing.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T612, Advanced OLAP operations	Oracle supports the following elements of this feature: PERCENT_RANK, CUME_DIST, WIDTH_BUCKET, hypothetical set functions, PERCENTILE_CONT, PERCENTILE_DISC, and ROW_NUMBER. Oracle does not support the following element of this feature: ROW_NUMBER without ORDER BY
T613, Sampling	Oracle uses the keyword SAMPLE instead of the standard's keyword, TABLESAMPLE. Oracle uses the keyword BLOCK instead of the standard's keyword, SYSTEM. Oracle uses the absence of the keyword BLOCK to indicate a Bernoulli sampling of rows, indicated in the standard by the keyword BERNOLLI. Oracle does not support sampling of derived tables or views that are not key-preserving. Oracle does not permit sampling in a subquery of a DELETE, UPDATE or MERGE statement.
T614, NTILE function	Oracle fully supports this feature.
T615, LEAD and LAG functions	Oracle fully supports this feature.
T616, Null treatment option for LEAD and LAG functions	Oracle fully supports this feature.
T617, FIRST_VALUE and LAST_VALUE functions	Oracle fully supports this feature.
T618, NTH_VALUE function	Oracle fully supports this feature.
T621, Enhanced numeric functions	Oracle fully supports this feature, except for the alternate spelling CEILING of the CEIL function.
T622, Trigonometric functions	Oracle fully supports this feature.
T623, General logarithm function	Oracle fully supports this feature.
T625, LISTAGG	Oracle fully supports this feature.
T641, Multiple column assignment	The standard syntax to assign to multiple columns is supported if the assignment source is a subquery.
T652, SQL-dynamic statements in SQL routines.	PL/SQL supports dynamic SQL.
T654, SQL-dynamic statements in external routines	Oracle supports dynamic SQL in embedded C, which may be used to create an external routine.
T655, Cyclically dependent routines	PL/SQL supports recursion.
T811, Basic SQL/JSON constructor functions	Oracle fully supports this feature, except for the JSON_ARRAY constructor by query.
T812, SQL/JSON: JSON_OBJECTAGG	Oracle fully supports this feature.
T813, SQL/JSON: JSON_ARRAYAGG with ORDER BY	Oracle fully supports this feature.
T821, Basic SQL/JSON query operators	Oracle fully supports this feature.
T822, SQL/JSON: IS JSON WITH UNIQUE KEYS predicate	Oracle fully supports this feature.

Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation

Feature ID	Feature Support
T823, SQL/JSON: PASSING clause	Oracle supports the PASSING clause in JSON_EXISTS.
T825, SQL/JSON: ON EMPTY and ON ERROR clauses	Oracle fully supports this feature, except that: - The ON ERROR clause for JSON_EXISTS does not support UNKNOWN. - JSON_TABLE does not support a column-level ON EMPTY clause.
T828, JSON_QUERY	Oracle fully supports this feature.
T829, JSON_QUERY: array wrapper options	Oracle fully supports this feature.
T832, SQL/JSON path language: item method	Oracle fully supports the following item methods: - abs - ceiling - double - floor Oracle provides the following comparable support: - date and timestamp are comparable to the standard's datetime Oracle extends this feature by supporting the following item methods: - length - lower - number - string - upper
T833, SQL/JSON path language: multiple subscripts	Oracle fully supports this feature, except that subscripts have to be specified in strictly monotonically increasing order.
T834, SQL/JSON path language: wildcard member accessor	Oracle fully supports this feature.
T835, SQL/JSON path language: filter expression	Oracle supports the filter expression as the last step of the SQL/JSON path expression in JSON_EXISTS.
T839, Formatted cast of datetimes to/from character strings	Oracle supports this feature with a minor syntactic difference: Oracle uses a comma instead of the keyword FORMAT.

Oracle Compliance with SQL/CLI

The Oracle ODBC driver conforms to SQL/CLI.

Oracle Compliance with SQL/PSM

Oracle PL/SQL provides functionality equivalent to SQL/PSM, with minor syntactic differences, such as the spelling or arrangement of keywords.

Oracle Compliance with SQL/MED

Oracle does not comply with SQL/MED.

Oracle Compliance with SQL/OLB

Oracle SQLJ conforms to SQL/OLB:1999 and not yet to SQL/OLB:2016.

Oracle Compliance with SQL/JRT

Oracle fully supports stored routines and SQL types implemented in Java(TM). Oracle provides equivalent support for the creation and maintenance of such types and procedures. Oracle's capabilities are in general a superset of the functionality defined by the standard.

Oracle Compliance with SQL/XML

The XML data type in the standard is XML. The Oracle equivalent data type is XMLType. A feature of the standard is considered to be fully supported if the only difference between Oracle and the standard is the spelling of the data type name.

[Table C-3](#) describes Oracle's support for the features of SQL/XML.

Table C-3 Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X010, XML type	Oracle fully supports this feature.
X011, Arrays of XML types	Oracle supports this feature using named array types
X012, Multisets of XML type	The Oracle equivalent of a multiset of XML type is a nested table with a single column of XML type.
X013, Distinct types of XML	A distinct type can be emulated using an object type with a single attribute.
X014, Attributes of XML type	In Oracle, attributes of object types may be of type XMLType, but the syntax for creating object types is nonstandard.
X015, Fields of XML type	Oracle object types may be used instead of row types; Oracle supports object types with attributes of XMLType.
X016, Persistent XML values	Oracle fully supports this feature.
X020, XMLConcat	Oracle fully supports this feature.
X025, XMLCast	Oracle supports this feature, with the following restrictions: - The source expression must be of XMLType and the target data type may not be XMLType. (Since Oracle has only one XML type, there is no need to cast from XML to XML.) - Oracle does not support <XML passing mechanism>; the behavior is the same as BY VALUE in the standard. Oracle extends this feature with the ability to cast to type REF XMLTYPE.
X031, XMLElement	Oracle fully supports this feature.
X032, XMLForest	Oracle fully supports this feature.
X034, XMLAgg	Oracle fully supports this feature.
X035, XMLAgg: ORDER BY option	Oracle fully supports this feature.
X036, XMLComment	Oracle fully supports this feature.
X036, XMLPi	Oracle fully supports this feature.

Table C-3 (Cont.) Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X038, XMLText	The Oracle XMLCDATA function may be used to create a text node.
X040, Basic table mapping	Oracle table mappings are available through a Java interface and through a package. Oracle table mappings have been generalized to map queries and not just tables. To map only a table: <code>SELECT * FROM table_name</code>. This provides support for the following elements of this feature: • X041, Basic table mapping: null absent • X042, Basic table mapping: null as nil • X043, Basic table mapping: table as forest • X044, Basic table mapping: table as element • X045, Basic table mapping: with target namespace • X046, Basic table mapping: data mapping • X047, Basic table mapping: metadata mapping • X049, Basic table mapping: hex encoding Oracle does not support the following element of this feature: • X048, Basic table mapping: base64 encoding
X041, Basic table mapping: null absent	See X040.
X042, Basic table mapping: null as nil	See X040.
X043, Basic table mapping: table as forest	See X040.
X044, Basic table mapping: table as element	See X040.
X045, Basic table mapping: with target namespace	See X040.
X046, Basic table mapping: data mapping	See X040.
X047, Basic table mapping: metadata mapping	See X040.
X049, Basic table mapping: hex encoding	See X040.
X060, XMLParse: Character string input and CONTENT option	Oracle does not support the {PRESERVE STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE.
X061, XMLParse: Character string input and DOCUMENT option	Oracle does not support the {PRESERVE STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE.
X069, XMLSERIALIZE: INDENT	Oracle extends this feature with the ability to specify an indent size.
X070, XMLSerialize: Character string serialization and CONTENT option	Oracle supports this feature, with this restriction: • In the standard, the choice of DOCUMENT or CONTENT is optional; in Oracle, you must specify one of these. Oracle extends this feature as follows: the standard requires a target data type; Oracle defaults to CLOB.
X071, XMLSerialize: Character string serialization and DOCUMENT option	Oracle fully supports this feature.

Table C-3 (Cont.) Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X072, XMLSerialize: Character string serialization	Oracle fully supports this feature.
X073, XMLSerialize: BLOB serialization and CONTENT option	Oracle fully supports this feature.
X074, XMLSerialize: BLOB serialization and DOCUMENT option	Oracle fully supports this feature.
X075, XMLSerialize: BLOB serialization	Oracle fully supports this feature.
X076, XMLSerialize: VERSION option	Oracle fully supports this feature.
X077, XMLSerialize: explicit ENCODING option	Oracle fully supports this feature.
X080, Namespaces in XML publishing	In the Oracle implementation of XMLElement, XMLAttributes are used to define namespaces (XMLNamespaces is not implemented). However, XMLAttributes is not supported for XMLForest.
X086, XML namespace declarations in XMLTable	Oracle fully supports this feature.
X090, XML document predicate	In Oracle, you can test whether an XML value is a document by using the ISFRAGMENT method.
X096, XMExists	Oracle fully supports this feature, with this exception: Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.
X120, XML parameters in SQL routines	Oracle fully supports this feature.
X121, XML parameters in external routines	Oracle supports XML values passed to external routines using a non-standard interface.
X141, IS VALID predicate: data drive case	The XMLISVALID method is equivalent to the IS VALID predicate, and supports the data-driven case.
X142, IS VALID predicate: ACCORDING TO clause	The XMLISVALID method is equivalent to the IS VALID predicate, and includes the equivalent of the ACCORDING TO clause.
X143, IS VALID predicate: ELEMENT clause	The XMLISVALID method is equivalent to the IS VALID predicate, and includes the equivalent of the ELEMENT clause.
X144, IS VALID predicate: schema location	The XMLISVALID method is equivalent to the IS VALID predicate, and supports the specification of a schema location for a registered XML Schema.
X145, IS VALID predicate outside check constraints	The XMLISVALID method is equivalent to the IS VALID predicate, and may be used outside check constraints.
X151, IS VALID predicate with DOCUMENT option	The XMLISVALID method is equivalent to the IS VALID predicate, and performs validation equivalent to the DOCUMENT clause. (XMLISVALID does not support "content" validation.)
X156, IS VALID predicate: optional NAMESPACE with ELEMENT clause	The XMLISVALID method is equivalent to the IS VALID predicate, and may be used to validate against an element in any namespace.

Table C-3 (Cont.) Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X157, IS VALID predicate: NO NAMESPACE with ELEMENT clause	The XMLISVALID method is equivalent to the IS VALID predicate, and may be used to validate against an element in the "no name" namespace.
X160, Basic Information Schema for registered XML Schemas	The Oracle static data dictionary view ALL_XML_SCHEMAS provides a list of the registered XML schemas that are accessible to the current user. The ALL_XML_SCHEMAS.SCHEMA_URL column corresponds to the standard XML_SCHEMAS.XML_SCHEMA_LOCATION column. The target namespace of the registered XML Schemas can be learned by examining ALL_XML_SCHEMAS.SCHEMA. Oracle has no equivalents for the other columns of the standard's XML_SCHEMAS.
X161, Advanced Information Schema for registered XML Schemas	Oracle does not have static data dictionary views corresponding to XML_SCHEMA_NAMESPACES and XML_SCHEMA_ELEMENTS in the standard. However, all the information about registered XML Schemas may be learned by examining the actual XML Schema, which is found in the ALL_XML_SCHEMAS.SCHEMA column. This may also be examined to learn whether a registered XML Schema is nondeterministic, and which of its namespaces and elements are nondeterministic.
X191, XML(DOCUMENT (XMLSCHEMA)) type	Oracle does not support this syntax. However, a column of a table can be constrained by a registered XML Schema, in which case all values of the column will be of XML(DOCUMENT(XMLSCHEMA)) type.
X200, XMLQuery	Oracle fully supports the following elements of this feature: • X201, XMLQuery: RETURNING CONTENT • X203, XMLQuery: passing a context item • X204, XMLQuery: initializing an XQuery variable • X206, XMLQuery: NULL ON EMPTY option Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.
X201, XMLQuery: RETURNING CONTENT	See X200.
X203, XMLQuery: passing a context item	See X200.
X204, XMLQuery: initializing an XQuery variable	See X200.
X206, XMLQuery: NULL ON EMPTY option	See X200.
X221, XML passing mechanism BY VALUE	Oracle supports the BY VALUE clause in XMLQuery, XMLTable and XMLExists. In these, BY VALUE is supported as optional syntax at the beginning of an argument list, but not as a modifier on an individual argument or column.
X232, XML(CONTENT(ANY)) type	Oracle does not support this syntax as a type modifier, but the Oracle XMLType supports this data type for transient values. Persistent values are of type XML(DOCUMENT(ANY)), which is a subset of XML(CONTENT(ANY)).

Table C-3 (Cont.) Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X241, RETURNING CONTENT in XML publishing	Oracle does not support this syntax. In Oracle, the behavior of the publishing functions (XMLAgg, XMLComment, XMLConcat, XMLElement, XMLForest, and XMLPi) is always RETURNING CONTENT.
X251, Persistent XML values of XML(DOCUMENT(UNTYPED)) type	Oracle fully supports this feature.
X252, Persistent values of type XML(DOCUMENT(ANY))	Oracle fully supports this feature.
X256, Persistent values of XML(DOCUMENT(XMLSCHEMA)) type	Oracle fully supports this feature.
X260, XML type, ELEMENT clause	Oracle does not support this syntax. However, a column of a table may be constrained by a top-level element in a registered XML Schema.
X263, XML type: NO NAMESPACE with ELEMENT clause	Oracle does not support this syntax. However, a column of a table may be constrained by a top-level element in the "no name" namespace of a registered XML Schema.
X264, XML type: schema location	Oracle does not support this syntax. However, a column of a table may be constrained by a registered XML Schema that is identified by a schema location.
X271, XMLValidate: data driven case	The SCHEMAVALIDATE method is equivalent to XMLValidate, and supports the data-driven case.
X272, XMLValidate: ACCORDING TO clause	The SCHEMAVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular registered XML Schema.
X273, XMLValidate: ELEMENT clause	The SCHEMAVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular element of a particular registered XML Schema.
X274, XMLValidate: schema location	The SCHEMAVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular registered XML Schema by its schema location URL.
X281, XMLValidate with DOCUMENT option	The SCHEMAVALIDATE method is equivalent to XMLValidate. SCHEMAVALIDATE performs validation only of XML documents (not content).
X286, XMLValidate: NO NAMESPACE with ELEMENT clause	The SCHEMAVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular element in the "no name" namespace of a particular registered XML Schema.
X300, XMLTable	Oracle does not support reverse axes in the column path expressions. Aside from that restriction, Oracle fully supports the following elements of this feature: • X086, XML namespace declarations in XMLTable • X302, XMLTable with ordinality column • X303, XMLTable: column default option • X304, XMLTable: passing a context item • X305, XMLTable: initializing an XQuery variable Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.

Table C-3 (Cont.) Oracle Support for Features of SQL/XML

Feature ID	Feature Support
X302, XMLTable with ordinality column	See X300.
X303, XMLTable: column default option	See X300.
X304, XMLTable: passing a context item	See X300.
X305, XMLTable: initializing an XQuery variable	See X300.

Oracle Compliance with SQL/MDA

Oracle does not comply with SQL/MDA.

Oracle Compliance with SQL/PGQ

Table [Table C-4](#) describes Oracle's support for the features of SQL/PGQ.

Table C-4 Oracle Support for Features of SQL/PGQ

Feature ID	Feature Support
G000, Graph pattern	Oracle fully supports this feature.
G001, Repeatable-elements match mode	Oracle fully supports this feature.
G008, Graph pattern WHERE clause	Oracle fully supports this feature.
G034, Path concatenation	Oracle fully supports this feature.
G035, Quantified paths	Oracle fully supports this feature.
G036, Quantified edges	Oracle fully supports this feature.
G037, Questioned paths	Oracle fully supports this feature.
G040, Vertex pattern	Oracle fully supports this feature.
G042, Basic full edge patterns	Oracle fully supports this feature.
G044, Basic abbreviated edge patterns	Oracle fully supports this feature.
G060, Bounded graph pattern quantifiers	Oracle fully supports this feature.
G070, Label expression: label disjunction	Oracle fully supports this feature.
G071, Label expression: label conjunction	Oracle provides equivalent functionality using label expressions on different graph patterns with the same graph element variable name.
G073, Label expression: individual label name	Oracle fully supports this feature.
G090, Property reference	Oracle fully supports this feature.
G100, ELEMENT_ID function	Oracle provides equivalent functionality using EDGE_ID and VERTEX_ID operators.
G112, IS SOURCE and IS DESTINATION predicate	Oracle fully supports this feature.

Table C-4 (Cont.) Oracle Support for Features of SQL/PGQ

Feature ID	Feature Support
G114, SAME predicate	Oracle provides equivalent functionality using VERTEX_EQUAL and EDGE_EQUAL predicates.
G120, Within-match aggregates	Oracle fully supports this feature.
G900, GRAPH_TABLE	Oracle fully supports this feature.
G904, All properties reference	Oracle supports this feature in the COLUMNS clause.
G920, DDL-based SQL-property graphs	Oracle fully supports this feature with the following exception: the keyword RESTRICT is not supported for the DROP PROPERTY GRAPH statement.
G924, Explicit key clause for element tables	Oracle fully supports this feature.
G925, Explicit label and properties clause for element tables	Oracle fully supports this feature.
G926, More than one label for vertex tables	Oracle fully supports this feature.
G927, More than one label for edge tables	Oracle fully supports this feature.
G928, Value expressions as properties and renaming of properties	Oracle fully supports this feature.
G929, Labels and properties: EXCEPT list	Oracle fully supports this feature.
G940, Multi-sourced and multi-destined edges	Oracle fully supports this feature.
G941, Implicit removal of incomplete edges	Oracle fully supports this feature.

Oracle Compliance with FIPS 127-2

Oracle complied fully with last Federal Information Processing Standard (FIPS), which was FIPS PUB 127-2. That standard is no longer published. However, for users whose applications depend on information about the sizes of some database constructs that were defined in FIPS 127-2, the details of our compliance are listed in [Table C-5](#).

Table C-5 Sizing for Database Constructs

Database Constructs	FIPS	Oracle Database
Length of an identifier (in bytes)	18	128
Length of CHARACTER data type (in bytes)	240	2,000
Decimal precision of NUMERIC data type	15	38
Decimal precision of DECIMAL data type	15	38
Decimal precision of INTEGER data type	9	38
Decimal precision of SMALLINT data type	4	38
Binary precision of FLOAT data type	20	126
Binary precision of REAL data type	20	63
Binary precision of DOUBLE PRECISION data type	30	126
Columns in a table	100	1,000
Values in an INSERT statement	100	1,000

Table C-5 (Cont.) Sizing for Database Constructs

Database Constructs	FIPS	Oracle Database
SET clauses in an UPDATE statement (Note 1)	20	1,000
Length of a row (Note 2, Note 3)	2,000	2,000,000
Columns in a UNIQUE constraint	6	32
Length of a UNIQUE constraint (Note 2)	120	(Note 4)
Length of foreign key column list (Note 2)	120	(Note 4)
Columns in a GROUP BY clause	6	255 (Note 5)
Length of GROUP BY column list	120	(Note 5)
Sort specifications in ORDER BY clause	6	255 (Note 5)
Length of ORDER BY column list	120	(Note 5)
Columns in a referential integrity constraint	6	32
Tables referenced in a SQL statement	15	No limit
Cursors simultaneously open	10	(Note 6)
Items in a SELECT list	100	1,000

Note 1: The number of SET clauses in an UPDATE statement refers to the number items separated by commas following the SET keyword.

Note 2: The FIPS PUB defines the length of a collection of columns to be the sum of: twice the number of columns, the length of each character column in bytes, decimal precision plus 1 of each exact numeric column, binary precision divided by 4 plus 1 of each approximate numeric column.

Note 3: The Oracle limit for the maximum row length is based on the maximum length of a row containing a LONG value of length 2 gigabytes and 999 VARCHAR2 values, each of length 4000 bytes: $2(254) + 231 + (999(4000))$.

Note 4: The Oracle limit for a UNIQUE key is half the size of an Oracle data block (specified by the initialization parameter DB_BLOCK_SIZE) minus some overhead.

Note 5: Oracle places no limit on the number of columns in a GROUP BY clause or the number of sort specifications in an ORDER BY clause. However, the sum of the sizes of all the expressions in either a GROUP BY clause or an ORDER BY clause is limited to the size of an Oracle data block (specified by the initialization parameter DB_BLOCK_SIZE) minus some overhead.

Note 6: The Oracle limit for the number of cursors simultaneously opened is specified by the initialization parameter OPEN_CURSORS. The maximum value of this parameter depends on the memory available on your operating system and exceeds 100 in all cases.

Oracle Extensions to Standard SQL

Oracle supports numerous features that extend beyond standard SQL. If you are concerned with the portability of your applications to other implementations of SQL, then use Oracle's FIPS Flagger to help identify the use of Oracle extensions to Entry SQL-92 in your embedded SQL programs. The FIPS Flagger is part of the Oracle precompilers and the SQL*Module compiler. The FIPS Flagger can also be enabled in SQL*Plus by using ALTER SESSION SET FLAGGER = ENTRY. While SQL-92 has been superseded by newer editions of the SQL Standard,

there has been no conformance testing authority for any version of SQL since SQL-92; hence, Entry SQL-92 offers you the most assurance of portability.

① See Also

*Pro*COBOL Programmer's Guide* and *Pro*C/C++ Programmer's Guide* for information on how to use the FIPS Flagger

Oracle Compliance with Older Standards

This release of Oracle Database conforms to SQL:2016, the most recent edition of the SQL standard when this guide was published, as itemized in preceding sections of this appendix. Oracle does not formally claim that this release of the database conforms to SQL-92—and in particular, to SQL-92 Entry Level—or to SQL:1999, because those standards have been superseded by SQL:2016. Some, mostly minor, changes between editions of the SQL standard might affect applications. The SQL standard, or a reference discussing that standard, can be consulted to determine the details of any incompatibilities that have been introduced. One important source is Annex E of SQL/Foundation:1999, SQL/Foundation:2003, SQL/Foundation:2008, SQL/Foundation:2011, and SQL/Foundation:2016.

In some cases, this release of Oracle Database might continue to recognize constructs from older editions of SQL. Such recognition is often allowed as a valid vendor extension. It is the general policy of Oracle to keep incompatibilities between versions of the database as few as possible. This policy extends to retention of older forms when that is feasible. In any case, the differences between older SQL and SQL:2016 (as noted above) are relatively inconsequential.

Character Set Support

Oracle supports most national, international, and vendor-specific encoded character set standards. A complete list of character sets supported by Oracle appears in *Oracle Database Globalization Support Guide*.

Unicode is a universal encoded character set that lets you store information from any language using a single character set. Unicode is required by modern standards such as XML, Java, JavaScript, and LDAP. Unicode is compliant with ISO/IEC standard 10646. For information on ISO standards, visit the Web site of the International Organization for Standardization:

<http://www.iso.ch/>

Oracle Database Release 23 complies with version 15.0 of the Unicode Standard. For up-to-date information on the Unicode Standard, visit the Web site of the Unicode Consortium:

<http://www.unicode.org>

Oracle supports the UTF-8 encoding scheme of the Unicode Standard through the AL32UTF8 character set, the UTF-16BE encoding scheme through the AL16UTF16 character set, and the UTF-16LE encoding scheme through the AL16UTF16LE character set. AL32UTF8 is valid as the client and database character set on ASCII-based platforms. AL16UTF16 is valid as the national (NCHAR) character set on all platforms. AL16UTF16LE is not valid as the client, database, or national character set.

Oracle implements two deprecated Unicode compatibility encoding forms: CESU-8 through the UTF8 character set and UTF-EBCDIC through the UTFE character set. The UTF8 and UTFE character sets are not guaranteed to include updates to the Unicode standard beyond version

3.0. UTF8 is valid as the client and database character set on ASCII-based platforms and as the national (NCHAR) character set on all platforms. UTFE is valid as the database character set on EBCDIC-based platforms.

All mentioned Oracle character sets are supported in conversion functions.

Oracle recommends that databases on ASCII-based platforms are created with the AL32UTF8 character set and the AL16UTF16 national (NCHAR) character set. Oracle recommends that you avoid the use of the NCHAR data types and the associated national character set as they are not supported by some RDBMS components, such as Oracle Text and Oracle XDB.

Oracle Database Globalization Support Guide for details on Oracle character set support

D

Oracle Regular Expression Support

Oracle's implementation of regular expressions conforms with the IEEE Portable Operating System Interface (POSIX) regular expression standard and to the Unicode Regular Expression Guidelines of the Unicode Consortium.

This appendix contains the following sections:

- [Multilingual Regular Expression Syntax](#)
- [Regular Expression Operator Multilingual Enhancements](#)
- [Perl-influenced Extensions in Oracle Regular Expressions](#)

Multilingual Regular Expression Syntax

[Table D-1](#) lists the full set of operators defined in the POSIX standard Extended Regular Expression (ERE) syntax. Oracle follows the exact syntax and matching semantics for these operators as defined in the POSIX standard for matching ASCII (English language) data. For more complete descriptions of the operators, examples of their use, and Oracle multilingual enhancements of the operators, refer to *Oracle Database Development Guide*. Notes following the table provide more complete descriptions of the operators and their functions, as well as Oracle multilingual enhancements of the operators. [Table D-2](#) summarizes Oracle support for and multilingual enhancement of the POSIX operators.

Table D-1 Regular Expression Operators and Metasymbols

Operator	Description
\	The backslash character can have four different meanings depending on the context. It can: • Stand for itself • Quote the next character • Introduce an operator • Do nothing
*	Matches zero or more occurrences
+	Matches one or more occurrences
?	Matches zero or one occurrence
	Alternation operator for specifying alternative matches
^	Matches the beginning of a string by default. In multiline mode, it matches the beginning of any line anywhere within the source string.
\$	Matches the end of a string by default. In multiline mode, it matches the end of any line anywhere within the source string.
.	Matches any character in the supported character set except NULL

Table D-1 (Cont.) Regular Expression Operators and Metasymbols

Operator	Description
[]	Bracket expression for specifying a matching list that should match any one of the expressions represented in the list. A non-matching list expression begins with a circumflex (^) and specifies a list that matches any character except for the expressions represented in the list. To specify a right bracket (]) in the bracket expression, place it first in the list (after the initial circumflex (^), if any). To specify a hyphen in the bracket expression, place it first in the list (after the initial circumflex (^), if any), last in the list, or as an ending range point in a range expression.
()	Grouping expression, treated as a single subexpression
{m}	Matches exactly m times
{m,}	Matches at least m times
{m,n}	Matches at least m times but no more than n times
\n	The backreference expression (n is a digit between 1 and 9) matches the n th subexpression enclosed between '(' and ')' preceding the \n
[..]	Specifies one collation element, and can be a multicharacter element (for example, [.ch.] in Spanish)
[:]	Specifies character classes (for example, [:alpha:]). It matches any character within the character class.
[==]	Specifies equivalence classes. For example, [=a=] matches all characters having base letter 'a'.

Regular Expression Operator Multilingual Enhancements

When applied to multilingual data, Oracle's implementation of the POSIX operators extends beyond the matching capabilities specified in the POSIX standard. [Table D-2](#) shows the relationship of the operators in the context of the POSIX standard.

- The first column lists the supported operators.
- The second and third columns indicate whether the POSIX standard (Basic Regular Expression—BRE and Extended Regular Expression—ERE, respectively) defines the operator
- The fourth column indicates whether Oracle's implementation extends the operator's semantics for handling multilingual data.

Oracle lets you enter multibyte characters directly, if you have a direct input method, or you can use functions to compose the multibyte characters. You cannot use the Unicode hexadecimal encoding value of the form '\xxxx'. Oracle evaluates the characters based on the byte values used to encode the character, not the graphical representation of the character. All accented characters are considered word characters.

Table D-2 POSIX and Multilingual Operator Relationships

Operator	POSIX BRE syntax	POSIX ERE Syntax	Multilingual Enhancement
\	Yes	Yes	—

Table D-2 (Cont.) POSIX and Multilingual Operator Relationships

Operator	POSIX BRE syntax	POSIX ERE Syntax	Multilingual Enhancement
*	Yes	Yes	—
+	--	Yes	—
?	—	Yes	—
	—	Yes	—
^	Yes	Yes	Yes
\$	Yes	Yes	Yes
.	Yes	Yes	Yes
[]	Yes	Yes	Yes
()	Yes	Yes	—
{m}	Yes	Yes	—
{m,}	Yes	Yes	—
{m,n}	Yes	Yes	—
\n	Yes	Yes	Yes
[..]	Yes	Yes	Yes
[::]	Yes	Yes	Yes
[==]	Yes	Yes	Yes

Perl-influenced Extensions in Oracle Regular Expressions

Oracle Database regular expression functions and conditions accept a number of Perl-influenced operators that are in common use, although not part of the POSIX standard. [Table D-3](#) lists those operators. For more complete descriptions with examples, refer to *Oracle Database Development Guide*.

Table D-3 Perl-influenced Operators in Oracle Regular Expressions

Operator	Description
\d	A digit character.
\D	A nondigit character.
\w	A word character.
\W	A nonword character.
\s	A whitespace character.
\S	A non-whitespace character.
\A	Matches only at the beginning of a string, or before a newline character at the end of a string.
\Z	Matches only at the end of a string.
*?	Matches the preceding pattern element 0 or more times (nongreedy).
+?	Matches the preceding pattern element 1 or more times (nongreedy).
??	Matches the preceding pattern element 0 or 1 time (nongreedy).

Table D-3 (Cont.) Perl-influenced Operators in Oracle Regular Expressions

Operator	Description
{n}?	Matches the preceding pattern element exactly <i>n</i> times (nongreedy).
{n,}?	Matches the preceding pattern element at least <i>n</i> times (nongreedy).
{n,m}?	Matches the preceding pattern element at least <i>n</i> but not more than <i>m</i> times (nongreedy).

E

Oracle SQL Reserved Words and Keywords

This appendix contains the following sections:

- [Oracle SQL Reserved Words](#)
- [Oracle SQL Keywords](#)

Oracle SQL Reserved Words

This section lists Oracle SQL reserved words. You cannot use Oracle SQL reserved words as nonquoted identifiers. Quoted identifiers can be reserved words, although this is not recommended.

Note

In addition to the following reserved words, Oracle uses system-generated names beginning with "SYS_" for implicitly generated schema objects and subobjects. Oracle discourages you from using this prefix in the names you explicitly provide to your schema objects and subobjects to avoid possible conflict in name resolution.

The V\$RESERVED_WORDS data dictionary view provides additional information on each reserved word, including whether it is always reserved or is reserved only for particular uses. Refer to *Oracle Database Reference* for more information.

Words followed by an asterisk (*) are also ANSI reserved words.

Note 1: This keyword is only reserved for use as an attribute name.

Note 2: You cannot use the uppercase word ROWID, either quoted or nonquoted, as a column name. However, you can use the uppercase word as a quoted identifier that is not a column

name, and you can use the word with one or more lowercase letters (for example, "Rowid" or "rowid") as any quoted identifier, including a column name.

Oracle SQL Keywords

Oracle SQL keywords are not reserved. However, Oracle uses them internally in specific ways. Therefore, if you use these words as names for objects and object parts, then your SQL statements may be more difficult to read and may lead to unpredictable results.

You can obtain a list of keywords by querying the V\$RESERVED_WORDS data dictionary view. All keywords in the view that are not listed as always reserved or reserved for a specific use are Oracle SQL keywords. Refer to *Oracle Database Reference* for more information.

F

Extended Examples

The body of the *SQL Language Reference* contains examples for almost every reference topic. This appendix contains lengthy examples that are not appropriate in the context of a single SQL statement. These examples are intended to provide uninterrupted the series of steps that you would use to take advantage of particular Oracle functionality. They do not replace the syntax diagrams and semantics found for each individual SQL statement in the body of the reference. Use the cross-references provided to access additional information, such as privileges required and restrictions, as well as syntax.

This appendix contains the following sections:

- [Using Extensible Indexing](#)
- [Using XML in SQL Statements](#)

Using Extensible Indexing

This section provides examples of the steps entailed in a simple but realistic extensible indexing scenario.

Suppose you want to rank the salaries in the `HR.employees` table and then find those that rank between 10 and 20. You could use the `DENSE_RANK` function, as follows:

```
SELECT last_name, salary FROM
  (SELECT last_name, DENSE_RANK() OVER
    (ORDER BY salary DESC) rank_val, salary FROM employees)
WHERE rank_val BETWEEN 10 AND 20;
```

① **See Also**
[DENSE_RANK](#)

This nested query is somewhat complex, and it requires a full scan of the `employees` table as well as a sort. An alternative would be to use extensible indexing to achieve the same goal. The resulting query will be simpler. The query will require only an index scan and a table access by rowid, and will therefore perform much more efficiently.

The first step is to create the implementation type `position_im`, including method headers for index definition, maintenance, and creation. Most of the type body uses PL/SQL, which is shown in italics.

The type must be created with the `AUTHID CURRENT_USER` clause because of the `EXECUTE IMMEDIATE` statement inside the function `ODCIINDEXCREATE()`. By default that function runs with the definer rights. When the function is called in the subsequent creation of the domain index, the invoker does not have the same rights.

```

The next step is to create the functional implementation `function_for_position_between` for the operator that will be associated with the indextype. (The PL/SQL blocks are shown in parentheses.)

This function is for use with an index-based function evaluation. Therefore, it takes an index context and scan context as parameters.

① See Also

- *Oracle Database Data Cartridge Developer's Guide* for information on creating index-based functional implementation
- [CREATE FUNCTION](#) and *Oracle Database PL/SQL Language Reference*

```

CREATE OR REPLACE FUNCTION function_for_position_between
    (col NUMBER, lower_pos NUMBER, upper_pos NUMBER,
     indexctx IN SYS.ODCIIndexCtx,
     scanctx IN OUT position_im,
     scanflg IN NUMBER)
RETURN NUMBER AS
  rid          ROWID;
storage_tab_name VARCHAR2(65);
lower_bound_stmt VARCHAR2(2000);
upper_bound_stmt VARCHAR2(2000);

```

```

col_val_stmt      VARCHAR2(2000);
lower_bound       NUMBER;
upper_bound       NUMBER;
column_value      NUMBER;
BEGIN
  IF (indexctx.IndexInfo IS NOT NULL) THEN
    storage_tab_name := indexctx.IndexInfo.INDEXSCHEMA || '.' ||
                        indexctx.IndexInfo.INDEXNAME || '_STORAGE_TAB';
    IF (scanctx IS NULL) THEN
/* This is the first call. Open a cursor for future calls.
   First, do some error checking
*/
      IF (lower_pos > upper_pos) THEN
        RAISE_APPLICATION_ERROR(-20101,
          'Upper Position must be greater than or equal to Lower Position');
      END IF;
      IF (lower_pos <= 0) THEN
        RAISE_APPLICATION_ERROR(-20101,
          'Both Positions must be greater than zero');
      END IF;
/* Obtain the upper and lower value bounds for the range we're interested in.
*/
      upper_bound_stmt := 'Select MIN(col_val) FROM (Select /*+ INDEX_DESC(' ||
                          storage_tab_name || ') */ DISTINCT ' ||
                          'col_val FROM ' || storage_tab_name || ' ORDER BY ' ||
                          'col_val DESC) WHERE rownum <= ' || lower_pos;
      EXECUTE IMMEDIATE upper_bound_stmt INTO upper_bound;
      IF (lower_pos != upper_pos) THEN
        lower_bound_stmt := 'Select MIN(col_val) FROM (Select /*+ INDEX_DESC(' ||
                            storage_tab_name || ') */ DISTINCT ' ||
                            'col_val FROM ' || storage_tab_name ||
                            ' WHERE col_val < ' || upper_bound || ' ORDER BY ' ||
                            'col_val DESC) WHERE rownum <= ' ||
                            (upper_pos - lower_pos);
        EXECUTE IMMEDIATE lower_bound_stmt INTO lower_bound;
      ELSE
        lower_bound := upper_bound;
      END IF;
      IF (lower_bound IS NULL) THEN
        lower_bound := upper_bound;
      END IF;
/* Store the lower and upper bounds for future function invocations for
   the positions.
*/
      scanctx := position_im(0, 0, lower_bound, upper_bound);
    END IF;
/* Fetch the column value corresponding to the rowid, and see if it falls
   within the determined range.
*/
    col_val_stmt := 'Select col_val FROM ' || storage_tab_name ||
                    ' WHERE base_rowid = ''' || indexctx.Rid || '''';
    EXECUTE IMMEDIATE col_val_stmt INTO column_value;
    IF (column_value <= scanctx.upper_bound AND
        column_value >= scanctx.lower_bound AND
        scanflg = ODCICONST.RegularCall) THEN
      RETURN 1;
    ELSE
      RETURN 0;
    END IF;
  ELSE
    RAISE_APPLICATION_ERROR(-20101, 'A column that has a domain index of' ||
      'Position indextype must be the first argument');
  END IF;

```

```
END IF;  
END;  
/
```

Next, create the `position_between` operator, which uses the `function_for_position_between` function. The operator takes an indexed `NUMBER` column as the first argument, followed by a `NUMBER` lower and upper bound as the second and third arguments.

 See Also

[CREATE OPERATOR](#)

```
CREATE OR REPLACE OPERATOR position_between  
  BINDING (NUMBER, NUMBER, NUMBER) RETURN NUMBER  
  WITH INDEX CONTEXT, SCAN CONTEXT position_im  
  USING function_for_position_between;
```

In this `CREATE OPERATOR` statement, the `WITH INDEX CONTEXT, SCAN CONTEXT position_im` clause is included so that the index context and scan context are passed in to the functional evaluation, which is index based.

Now create the `position_indextype` indextype for the `position_operator`:

 See Also

[CREATE INDEXTYPE](#)

```
CREATE INDEXTYPE position_indextype  
  FOR position_between(NUMBER, NUMBER, NUMBER)  
  USING position_im;
```

The operator `position_between` uses an index-based functional implementation. Therefore, a domain index must be defined on the referenced column so that the index information can be passed into the functional evaluation. So the final step is to create the domain index `salary_index` using the `position_indextype` indextype:

 See Also

[CREATE INDEX](#)

```
CREATE INDEX salary_index ON employees(salary)  
  INDEXTYPE IS position_indextype;
```

Now you can use the `position_between` operator function to rewrite the original query as follows:

```
SELECT last_name, salary FROM employees  
  WHERE position_between(salary, 10, 20)=1  
  ORDER BY salary DESC, last_name;
```

LAST_NAME	SALARY

Using XML in SQL Statements

This section describes some of the ways you can use XMLType data in the database.

XMLType Tables

The sample schema oe contains a table warehouses, which contains an XMLType column warehouse_spec. Suppose you want to create a separate table with the warehouse_spec information. The following example creates a very simple XMLType table with one CLOB column:

```
CREATE TABLE xwarehouses OF XMLTYPE
XMLTYPE STORE AS CLOB;
```

You can insert into such a table using XMLType syntax, as shown in the next statement. (The data inserted in this example corresponds to the data in the warehouse_spec column of the sample table oe.warehouses where warehouse_id = 1.)

```
INSERT INTO xwarehouses VALUES
(xmltype('<?xml version="1.0"?>
<Warehouse>
  <WarehouseId>1</WarehouseId>
  <WarehouseName>Southlake, Texas</WarehouseName>
  <Building>Owned</Building>
  <Area>25000</Area>
  <Docks>2</Docks>
  <DockType>Rear load</DockType>
  <WaterAccess>true</WaterAccess>
  <RailAccess>N</RailAccess>
  <Parking>Street</Parking>
  <VClearance>10</VClearance>
</Warehouse>'));
```

① See Also

Oracle XML DB Developer's Guide for information on XMLType and its member methods

You can query this table with the following statement:

```
SELECT e.getClobVal() FROM xwarehouses e;
```

CLOB columns are subject to all of the restrictions on LOB columns. To avoid these restrictions, create an XMLSchema-based table. The XMLSchema maps the XML elements to their object-relational equivalents. The following example registers an XMLSchema locally. The XMLSchema (*xwarehouses.xsd*) reflects the same structure as the *xwarehouses* table. (XMLSchema declarations use PL/SQL and the DBMS_XMLSCHEMA package, so the example is shown in italics.)

① See Also

Oracle XML DB Developer's Guide for information on creating XMLSchemas

```
begin
  dbms_xmlschema.registerSchema(
    'http://www.example.com/xwarehouses.xsd',
    '<schema xmlns="http://www.w3.org/2001/XMLSchema"
      targetNamespace="http://www.example.com/xwarehouses.xsd"
      xmlns:who="http://www.example.com/xwarehouses.xsd"
      version="1.0">

    <simpleType name="RentalType">
      <restriction base="string">
        <enumeration value="Rented"/>
        <enumeration value="Owned"/>
      </restriction>
    </simpleType>

    <simpleType name="ParkingType">
      <restriction base="string">
        <enumeration value="Street"/>
        <enumeration value="Lot"/>
      </restriction>
    </simpleType>

    <element name = "Warehouse">
      <complexType>
        <sequence>
          <element name = "WarehouseId" type = "positiveInteger"/>
          <element name = "WarehouseName" type = "string"/>
          <element name = "Building" type = "who:RentalType"/>
          <element name = "Area" type = "positiveInteger"/>
          <element name = "Docks" type = "positiveInteger"/>
          <element name = "DockType" type = "string"/>
          <element name = "WaterAccess" type = "boolean"/>
          <element name = "RailAccess" type = "boolean"/>
          <element name = "Parking" type = "who:ParkingType"/>
          <element name = "VClearance" type = "positiveInteger"/>
        </sequence>
```

```

        </complexType>
    </element>
</schema>',
    TRUE, TRUE, FALSE, FALSE);
end;
/

```

Now you can create an XMLSchema-based table, as shown in the following example:

```

CREATE TABLE xwarehouses OF XMLTYPE
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse";

```

By default, Oracle stores this as an object-relational table. Therefore, you can insert into it as shown in the example that follows. (The data inserted in this example corresponds to the data in the warehouse_spec column of the sample table oe.warehouses where warehouse_id = 1.)

```

INSERT INTO xwarehouses VALUES(    xmltype.createxml('<?xml version="1.0"?>
    <who:Warehouse xmlns:who="http://www.example.com/xwarehouses.xsd"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.example.com/xwarehouses.xsd
    http://www.example.com/xwarehouses.xsd">
        <WarehouseId>1</WarehouseId>
        <WarehouseName>Southlake, Texas</WarehouseName>
        <Building>Owned</Building>
        <Area>25000</Area>
        <Docks>2</Docks>
        <DockType>Rear load</DockType>
        <WaterAccess>true</WaterAccess>
        <RailAccess>false</RailAccess>
        <Parking>Street</Parking>
        <VClearance>10</VClearance>
    </who:Warehouse>')));
...

```

You can define constraints on an XMLSchema-based table. To do so, you use the XMLDATA pseudocolumn to refer to the appropriate attribute within the Warehouse XML element:

```

ALTER TABLE xwarehouses ADD (PRIMARY KEY(XMLDATA."WarehouseId"));

```

Because the data in xwarehouses is stored object relationally, Oracle rewrites queries to this XMLType table to go to the underlying storage when possible. Therefore the following queries would use the index created by the primary key constraint in the preceding example:

```

SELECT * FROM xwarehouses x
    WHERE EXISTSNODE(VALUE(x), '/Warehouse[WarehouseId="1"]',
        'xmlns:who="http://www.example.com/xwarehouses.xsd"' ) = 1;

SELECT * FROM xwarehouses x
    WHERE EXTRACTVALUE(VALUE(x), '/Warehouse/WarehouseId',
        'xmlns:who="http://www.example.com/xwarehouses.xsd"' ) = 1;

```

You can also explicitly create indexes on XMLSchema-based tables, which greatly enhance the performance of subsequent queries. You can create object-relational views on XMLType tables, and you can create XMLType views on object-relational tables.

① See Also

- [XMLDATA Pseudocolumn](#) for information on the XMLDATA pseudocolumn
- ["Creating an XMLType View: Example"](#)
- [Creating an Index on an XMLType Table: Example](#)

XMLType Columns

The sample table `oe.warehouses` was created with a `warehouse_spec` column of type XMLType. The examples in this section create a shortened form of the `oe.warehouses` table, using two different types of storage.

The first example creates a table with an XMLType table stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```
CREATE TABLE xwarehouses (  
  warehouse_id      NUMBER,  
  warehouse_spec    XMLTYPE)  
XMLTYPE warehouse_spec STORE AS CLOB  
(TABLESPACE example  
  STORAGE (INITIAL 6144)  
  CHUNK 4000  
  NOCACHE LOGGING);
```

The following example creates a similar table, but stores the XMLType data in an object-relational XMLType column whose structure is determined by the specified XMLSchema:

```
CREATE TABLE xwarehouses (  
  warehouse_id      NUMBER,  
  warehouse_spec    XMLTYPE)  
XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL  
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"  
  ELEMENT "Warehouse";
```
